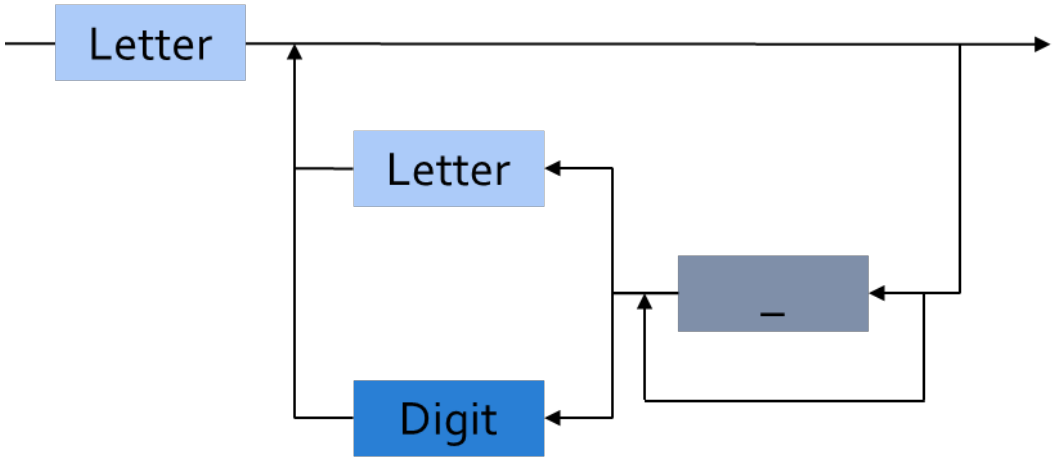
Declarations

Introduction

Identifiers



- Legal identifiers
  `Phase2`
  `A`
  `Space_Person`
- Not legal identifiers
  `Phase2__1`
  `A_`
  `_space_person`

String Literals

```
string_literal ::= "<string content>"
```

```
A_Null_String : constant string := "";
   -- two double quotes with nothing inside
String_Of_Length_One : constant string := "A";
Embedded_Single_Quotes : constant string :=
                           "Embedded 'single' quotes";
Embedded_Double_Quotes : constant string :=
                           "Embedded ""double"" quotes";
```

Identifiers, Comments, and Pragmas

Examples

```
package Identifiers_Comments_And_Pragmas is

   Spaceperson : Integer;
   --SPACEPERSON : integer; -- identifier is a duplicate
   Space_Person : Integer;
   --Null : integer := 0; -- identifier is a reserved word
   pragma Unreferenced (Spaceperson);
   pragma Unreferenced (Space_Person);

end Identifiers_Comments_And_Pragmas;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/020_declarations.html#identifiers-comments-and-pragmas

Identifiers

- Syntax

```
identifier ::= letter {[underline] letter_or_digit}
```

- Character set **Unicode** 4.0
  - 8, 16, 32 bit-wide characters
- Case **not significant**
  - **SpacePerson** $\Longleftrightarrow$ **SPACEPERSON**
  - but **different** from **Space_Person**
- Reserved words are **forbidden**

Reserved Words

abort
abs

xor

Comments

- Terminate at end of line (i.e., no comment terminator sequence)

```
-- This is a multi-
-- line comment
A : B; -- this is an end-of-line comment
```

Pragmas

- Compiler directives
  - Compiler action *not part of* Ada grammar
  - Only **suggestions**, may be **ignored**
  - Either standard or implementation-defined
- Unrecognized pragmas
  - **No effect**
  - Cause **warning** (standard mode)
- Malformed pragmas are **illegal**

```
pragma Page;
pragma Optimize ( Off );
```

Quiz

Which statement is legal?

A. `Function : constant := 1;`
B. `Fun_ction :  constant := 1;`
C. `Fun_ction : constant := --initial value-- 1;`
D. `integer Fun_ction;`

Quiz

Which statement is legal?

A. `Function : constant := 1;`
B. `Fun_ction :  constant := 1;`
C. `Fun_ction : constant := --initial value-- 1;`
D. `integer Fun_ction;`

Explanations

A. `function` is a reserved word
B. Correct
C. Cannot have inline comments
D. C-style declaration not allowed

Numeric Literals

Examples

```
package Numeric_Literals is

   Simple_Integer   : constant := 3;
   Decimal_Number   : constant := 0.25;
   Using_Separator  : constant := 1_000_000.0;
   Octal            : constant := 8#33#;
   Hexadecimal      : constant := 16#AAAA#;

end Numeric_Literals;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/020_declarations.html#numeric-literals

Decimal Numeric Literals

- Syntax

```
decimal_literal ::=
  numeral [.num] E [+numeral|-numeral]
numeral ::= digit {[underline] digit}
```

- Underscore is not significant
- **E** (exponent) must always be integer
- Examples

```
12      0      1E6          123_456
12.0    0.0    3.14159_26   2.3E-4
```

Based Numeric Literals

```
based_literal ::= base # numeral [.numeral] # exponent
numeral ::= base_digit { '_' base_digit }
```

- Base can be 2 .. 16
- Exponent is always a base 10 integer

```
16#FFF#             => 4095
2#1111_1111_1111#   => 4095 -- With underline
16#F.FF#E+2         => 4095.0
8#10#E+3            => 4096 (8 * 8**3)
```

Comparison To C's Based Literals

- Design in reaction to C issues
- C has **limited** bases support
  - Bases 8, 10, 16
  - No base 2 in standard
- Zero-prefixed octal `0nnn`
  - **Hard** to read
  - **Error-prone**

Quiz

Which statement is legal?

A. `I : constant := 0_1_2_3_4;`
B. `F : constant := 12.;`
C. `I : constant := 8#77#E+1.0;`
D. `F : constant := 2#1111;`

Quiz

Which statement is legal?

A. `I : constant := 0_1_2_3_4;`
B. `F : constant := 12.;`
C. `I : constant := 8#77#E+1.0;`
D. `F : constant := 2#1111;`

Explanations

A. Underscores are not significant - they can be anywhere (except first and last character, or next to another underscore)
B. Must have digits on both sides of decimal
C. Exponents must be integers
D. Missing closing #

Object Declarations

Examples

```
with Ada.Calendar; use Ada.Calendar;
package Object_Declarations is
   A    : Integer := 0;
   B, C : Time    := Clock;
   D    : Integer := A + 1;
end Object_Declarations;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/020_declarations.html#object-declarations

Declarations

- Associate a *name* to an *entity*
  - Objects
  - Types
  - Subprograms
  - et cetera
- Declaration **must precede** use
- **Some** implicit declarations
  - **Standard** types and operations
  - **Implementation**-defined

Object Declarations

- Variables and constants
- Basic Syntax

```
<name> : subtype_indication [:= <initial value>];
```

- Examples

```
Z, Phase : Analog;
Max : constant Integer := 200;
-- variable with a constraint
Count : Integer range 0 .. Max := 0;
-- dynamic initial value via function call
Root : Tree := F(X);
```

Multiple Object Declarations

- Allowed for convenience

```
A, B : Integer := Next_Available(X);
```

- Identical to series of single declarations

```
A : Integer := Next_Available(X);
B : Integer := Next_Available(X);
```

- Warning: may get different value

```
T1, T2 : Time := Current_Time;
```

Predefined Declarations

- **Implicit** declarations
- Language standard
- Annex A for *Core*
  - Package `Standard`
  - Standard types and operators
    - Numerical
    - Characters
  - About **half the RM** in size
- "Specialized Needs Annexes" for *optional*
- Also, implementation specific extensions

Implicit vs. Explicit Declarations

- Explicit → in the source

```
type Counter is range 0 .. 1000;
```

- Implicit → **automatically** by the compiler

```
function "+" ( Left, Right : Counter ) return Counter;
function "-" ( Left, Right : Counter ) return Counter;
function "*" ( Left, Right : Counter ) return Counter;
function "/" ( Left, Right : Counter ) return Counter;
...
```

Elaboration

- Effects of the declaration
  - **Initial value** calculations
  - *Execution* at **run-time** (if at all)
- Objects
  - Memory **allocation**
  - Initial value
- Linear elaboration
  - Follows the program text
  - Top to bottom

```
declare
   First_One : Integer := 10;
   Next_One : Integer := First_One;
   Another_One : Integer := Next_One;
begin
   ...
```

Quiz

Which block is illegal?

A.
```
A, B, C : integer;
```

B.
```
Integer : Standard.Integer;
```

C.
```
Null :  integer := 0;
```

D.
```
A : integer := 123;
B : integer := A * 3;
```

Quiz

Which block is illegal?

A.
```
A, B, C : integer;
```

B.
```
Integer : Standard.Integer;
```

C.
```
Null :  integer := 0;
```

D.
```
A : integer := 123;
B : integer := A * 3;
```

Explanations

A. Multiple objects can be created in one statement
B. `integer` is *predefined* so it can be overridden
C. `null` is *reserved* so it can **not** be overridden
D. Elaboration happens in order, so `B` will be 369

Universal Types

Universal Types

- Implicitly defined
- Entire *classes* of numeric types
  - **universal_integer**
  - **universal_real**
  - **universal_fixed**
- Match any integer / real type respectively
  - **Implicit** conversion, as needed

```
X : Integer64 := 2;
Y : Integer8 := 2;
```

Numeric Literals Are Universally Typed

- No need to type them
  - e.g `0UL` as in C
- Compiler handles typing
  - No bugs with precision

```
X : Unsigned_Long := 0;
Y : Unsigned_Short := 0;
```

Literals Must Match "Class" of Context

- **universal_integer** literals → **integer**
- **universal_real** literals → **fixed** or **floating** point
- Legal

```
X : Integer := 2;
Y : Float := 2.0;
```

- Not legal

```
X : Integer := 2.0;
Y : Float := 2;
```

Named Numbers

Examples

```
with Ada.Text_IO; use Ada.Text_IO;
procedure Named_Numbers is
   Universal_Third       : constant       := 1.0 / 3.0;
   Float_Third           : constant Float := 1.0 / 3.0;
   Float_Value           : Float;
   Long_Float_Value      : Long_Float;
   Long_Long_Float_Value : Long_Long_Float;
begin
   Float_Value           := Universal_Third;
   Long_Float_Value      := Universal_Third;
   Long_Long_Float_Value := Universal_Third;
   Put_Line (Float'Image (Float_Value));
   Put_Line (Long_Float'Image (Long_Float_Value));
   Put_Line (Long_Long_Float'Image (Long_Long_Float_Value));
   Float_Value           := Float_Third;
   Long_Float_Value      := Long_Float (Float_Third);
   Long_Long_Float_Value := Long_Long_Float (Float_Third);
   Put_Line (Float'Image (Float_Value));
   Put_Line (Long_Float'Image (Long_Float_Value));
   Put_Line (Long_Long_Float'Image (Long_Long_Float_Value));
end Named_Numbers;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/020_declarations.html#named-numbers

Named Numbers

- Associate a **name** with an **expression**
  - Used as **constant**
  - **universal_integer**, or **universal_real**
  - compatible with integer / real respectively
  - Expression must be **static**
- Syntax

```
<name> : constant := <static_expression>;
```

- Example

```
Pi : constant := 3.141592654;
One_Third : constant := 1.0 / 3.0;
```

A Sample Collection of Named Numbers

```
package Physical_Constants is
   Polar_Radius : constant := 20_856_010.51;
   Equatorial_Radius : constant := 20_926_469.20;
   Earth_Diameter : constant :=
     2.0 * ((Polar_Radius + Equatorial_Radius)/2.0);
   Gravity : constant := 32.1740_4855_6430_4;
   Sea_Level_Air_Density : constant :=
     0.002378;
   Altitude_Of_Tropopause : constant := 36089.0;
   Tropopause_Temperature : constant := -56.5;
end Physical_Constants;
```

Named Number Benefit

- Evaluation at **compile time**
  - As if **used directly** in the code
  - **Perfect** accuracy

```
Named_Number   : constant :=       1.0 / 3.0;
Typed_Constant : constant float := 1.0 / 3.0;
```

Object	Named_Number	Typed_Constant
`F32 : Float_32;`	3.33333E-01	3.33333E-01
`F64 : Float_64;`	3.33333333333333E-01	3.333333_43267441E-01
`F128 : Float_128;`	3.33333333333333333E-01	3.333333_43267440796E-01

Scope and Visibility

Examples

```
with Ada.Text_IO; use Ada.Text_IO;
procedure Scope_And_Visibility is
   Name : Integer;
begin
   Name := 1;
   declare
      Name : Float := 2.0;
   begin
      Name := Name + Float (Scope_And_Visibility.Name);
      Put_Line (Name'Image);
   end;
   Put_Line (Name'Image);
end Scope_And_Visibility;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/020_declarations.html#scope-and-visibility

Scope and Visibility

- *Scope* of a name
  - Where the name is **potentially** available
  - Determines **lifetime**
  - Scopes can be **nested**
- *Visibility* of a name
  - Where the name is **actually** available
  - Defined by **visibility rules**
  - **Hidden** $\rightarrow$ *in scope* but **not visible**

Introducing Block Statements

- **Sequence** of statements
  - Optional *declarative part*
  - Can be **nested**
  - Declarations **can hide** outer variables
- Syntax

```
[<block-name> :] declare
   <declarative part>
begin
   <statements>
end [block-name];
```

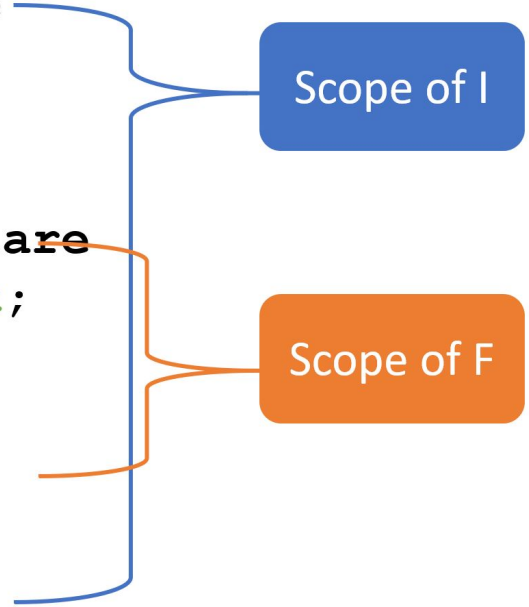
- Example

```
Swap: declare
   Temp : Integer;
begin
   Temp := U;
   U := V;
   V := Temp;
end Swap;
```

Scope and "Lifetime"

- Object in scope → exists
- No *scoping* keywords
  - C's **static**, **auto** etc...

```
Outer : declare
   I : Integer;
begin
   I := 1;
   Inner : declare
      F : Float;
   begin
      F := 1.0;
   end Inner;
   I := I + 1;
end Outer;
```



Name Hiding

- Caused by **homographs**
  - **Identical** name
  - **Different** entity

```
declare
   M : Integer;
begin
   ... -- M here is an INTEGER
   declare
      M : Float;
   begin
      ... -- M here is a FLOAT
   end;
   ... -- M here is an INTEGER
end;
```

Overcoming Hiding

- Add a **prefix**
  - Needs named scope
- Homographs are a *code smell*
  - May need **refactoring**...

```
Outer : declare
   M : Integer;
begin
   ...
   declare
      M : Float;
   begin
      Outer.M := Integer(M); -- Prefixed
   end;
   ...
end Outer;
```

Quiz

What output does the following code produce? (Assume `Print` prints the current value of its argument)

```
1  declare
2     M : Integer := 1;
3  begin
4     M := M + 1;
5     declare
6        M : Integer := 2;
7     begin
8        M := M + 2;
9        Print ( M );
10    end;
11    Print ( M );
12 end;
```

A. 2, 2
B. 2, 4
C. 4, 4
D. 4, 2

Quiz

What output does the following code produce? (Assume `Print` prints the current value of its argument)

```
1  declare
2     M : Integer := 1;
3  begin
4     M := M + 1;
5     declare
6        M : Integer := 2;
7     begin
8        M := M + 2;
9        Print ( M );
10    end;
11    Print ( M );
12 end;
```

A. 2, 2
B. 2, 4
C. 4, 4
D. ***4, 2***

Explanation

- Inner `M` gets printed first. It is initialized to 2 and incremented by 2
- Outer `M` gets printed second. It is initialized to 1 and incremented by 1

Aspect Clauses

Examples

```
package Aspect_Clauses is
   Eight_Bits : Integer range 0 .. 255 with
      Size => 8;
   Object : Integer with
      Atomic;
end Aspect_Clauses;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/020_declarations.html#aspect-clauses

Aspect Clauses

Ada 2012

- Define **additional** properties of an entity
  - Representation (eg. `Packed`)
  - Operations (eg. `Inline`)
  - Can be **standard** or **implementation**-defined
- Usage close to pragmas
  - More **explicit**, **typed**
  - **Cannot** be ignored
  - **Recommended** over pragmas
- Syntax
  - *Note:* always part of a **declaration**

```
with aspect_mark [ => expression]
     {, aspect_mark [ => expression] }
```

Aspect Clause Example: Objects

Ada 2012

- Updated **object syntax**

```
<name> : <subtype_indication> [:= <initial value>]
                 with aspect_mark [ => expression]
                 {, aspect_mark [ => expression] };
```

- Usage

```
CR1 : Control_Register with
   Size    => 8,
   Address => To_Address (16#DEAD_BEEF#);

-- Prior to Ada 2012
-- using *representation clauses*
CR2 : Control_Register;
for CR2'Size use 8;
for CR2'Address use To_Address (16#DEAD_BEEF#);
```

Boolean Aspect Clauses

Ada 2012

- **Boolean** aspects only
- Longhand

```
procedure Foo with Inline => True;
```

- Aspect name only → **True**

```
procedure Foo with Inline; -- Inline is True
```

- No aspect → **False**

```
procedure Foo; -- Inline is False
```

  - Original form!

Summary

Summary

- Declarations of a **single** type, permanently
  - OOP adds flexibility
- Named-numbers
  - **Infinite** precision, **implicit** conversion
- **Elaboration** concept
  - Value and memory initialization at **run-time**
- Simple **scope** and **visibility** rules
  - **Prefixing** solves **hiding** problems
- Pragmas, Aspects
- Detailed syntax definition in Annex P (using BNF)

Basic Types

Introduction

Ada Type Model

- *Static* Typing
  - Object type **cannot change**
- *Strong* Typing
  - By **name**
  - **Compiler-enforced** operations and values
  - **Explicit** conversion for "related" types
  - **Unchecked** conversions possible

Strong Typing

- Definition of *type*
  - Applicable **values**
  - Applicable *primitive* **operations**
- Compiler-enforced
  - **Check** of values and operations
  - Easy for a computer
  - Developer can focus on **earlier** phase: requirement

A Little Terminology

- **Declaration** creates a **type name**

```
type <name> is <type definition>;
```

- **Type-definition** defines its structure
  - Characteristics, and operations
  - Base "class" of the type

```
type Type_1 is digits 12; -- floating-point
type Type_2 is range -200 .. 200; -- signed integer
type Type_3 is mod 256; -- unsigned integer
```

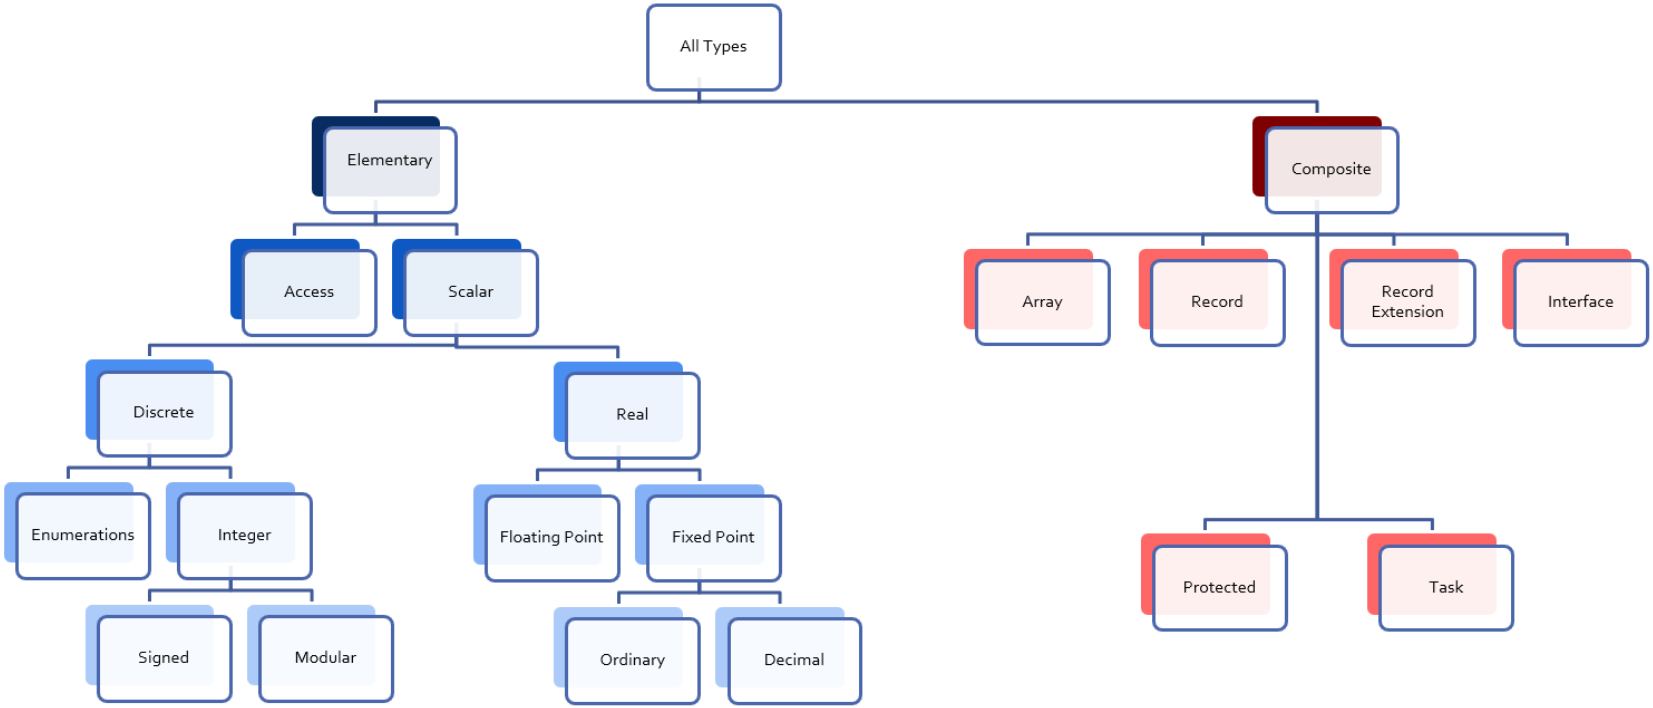
- *Representation* is the memory-layout of an **object** of the type

Ada "Named Typing"

- **Name** differentiate types
- Structure does **not**
- Identical structures may **not** be interoperable

```
type Yen is range 0 .. 100_000_000;
type Ruble is range 0 .. 100_000_000;
Mine : Yen;
Yours : Ruble;
...
Mine := Yours; -- not legal
```

Categories of Types



Scalar Types

- Indivisible: No components
- **Relational** operators defined (<, =, ...)
  - **Ordered**
- Have common **attributes**
- **Discrete** Types
  - Integer
  - Enumeration
- **Real** Types
  - Floating-point
  - Fixed-point

Discrete Types

- **Individual** ("discrete") values
  - 1, 2, 3, 4 ...
  - Red, Yellow, Green
- Integer types
  - Signed integer types
  - Modular integer types
    - Unsigned
    - **Wrap-around** semantics
    - Bitwise operations
- Enumeration types
  - Ordered list of **logical** values

Attributes

- Functions *associated* with a type
  - May take input parameters
- Some are language-defined
  - *May* be implementation-defined
  - **Built-in**
  - Cannot be user-defined
  - Cannot be modified
- See RM K.2 *Language-Defined Attributes*
- Syntax

```
Type_Name'Attribute_Name;
Type_Name'Attribute_With_Param (Param);
```

- ' often named *tick*

Discrete Numeric Types

Examples

```
with Ada.Text_IO; use Ada.Text_IO;
procedure Discrete_Numeric_Types is

   type Signed_Integer_Type is range -128 .. 127;
   Signed_Integer : Signed_Integer_Type := 100;

   type Unsigned_Integer_Type is mod 256;
   Unsigned_Integer : Unsigned_Integer_Type := 100;

begin

   Signed_Integer := Signed_Integer_Type'Last;
   Signed_Integer := Signed_Integer_Type'Succ (Signed_Integer);
   Put_Line (Signed_Integer'Image);

   Unsigned_Integer := Unsigned_Integer_Type'First;
   Unsigned_Integer := Unsigned_Integer_Type'Pred (Unsigned_Integer);
   Put_Line (Unsigned_Integer'Image);

   Unsigned_Integer := Unsigned_Integer_Type (Signed_Integer);
   Put_Line (Unsigned_Integer'Image);

   Unsigned_Integer := Unsigned_Integer_Type'Mod (Signed_Integer);
   Put_Line (Unsigned_Integer'Image);

   declare
      Some_String : constant String :=
        Unsigned_Integer_Type'Image (Unsigned_Integer);
   begin
      Signed_Integer := Signed_Integer_Type'Value (Some_String);
      Put_Line (Signed_Integer'Image);

      Put_Line (Some_String);
   end;

end Discrete_Numeric_Types;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/030_basic_types.html#discrete-numeric-types

Signed Integer Types

- Range of signed **whole** numbers
  - Symmetric about zero (-0 = +0)
- Syntax

```
type <identifier> is range  <lower> .. <upper>;
```

- Implicit numeric operators

```
-- 12-bit device
type Analog_Conversions is range 0 .. 4095;
Count : Analog_Conversions;
...
begin
   ...
   Count := Count + 1;
   ...
end;
```

Specifying Integer Type Bounds

- Must be **static**
  - Compiler selects **base type**
  - Hardware-supported integer type
  - Compilation **error** if not possible

Predefined Integer Types

- `Integer` >= **16 bits** wide
- Other **probably** available
  - `Long_Integer`, `Short_Integer`, etc.
  - Guaranteed ranges: `Short_Integer` <= `Integer` <= `Long_Integer`
  - Ranges are all **implementation-defined**
- Portability not guaranteed
  - But may be difficult to avoid

Operators for Any Integer Type

- By increasing precedence

  relational operator `=` | `/=` | `<` | `<=` | `>` | `>=`

  binary adding operator `+` | `-`

  unary adding operator `+` | `-`

  multiplying operator `*` | `/` | **`mod`** | **`rem`**

  highest precedence operator `**` | **`abs`**

- *Note*: for exponentiation `**`
  - Result will be `Integer`
  - So power **must** be `Integer >= 0`
- Division by zero → `Constraint_Error`

Integer Overflows

- Finite binary representation
- Common source of bugs

```
K : Short_Integer := Short_Integer'Last;
...
K := K + 1;
```

```
 2#0111_1111_1111_1111#  = (2**16)-1

+                        1

=========================
 2#1000_0000_0000_0000#  = -32,768
```

Integer Overflow: Ada vs others

- Ada
  - `Constraint_Error` standard exception
  - Incorrect numerical analysis
- Java
  - Silently **wraps** around (as the hardware does)
- C/C++
  - **Undefined** behavior (typically silent wrap-around)

Modular Types

- Integer type
- **Unsigned** values
- Adds operations and attributes
  - Typically **bit-wise** manipulation
- Syntax

```
type <identifier> is mod <modulus>;
```

- Modulus must be **static**
- Resulting range is 0 .. modulus-1

```
type Unsigned_Word is mod 2**16; -- 16 bits, 0..65535
type Byte is mod 256;            -- 8 bits, 0..255
```

Modular Type Semantics

- Standard `Integer` operators
- **Wraps-around** in overflow
  - Like other languages' unsigned types
  - Attributes `'Pred` and `'Succ`
- Additional bit-oriented operations are defined
  - `and`, `or`, `xor`, `not`
  - **Bit shifts**
  - Values as **bit-sequences**

Predefined Modular Types

- In `Interfaces` package
  - Need **explicit** import
- **Fixed-size** numeric types
- Common name **format**
  - `Unsigned_n`
  - `Integer_n`

```
type Integer_8 is range -2 ** 7 .. 2 ** 7 - 1;
type Integer_16 is range -2 ** 15 .. 2 ** 15 - 1;
...
type Unsigned_8 is mod 2 ** 8;
type Unsigned_16 is mod 2 ** 16;
```

Integer Type (Signed and Modular) Literals

- **Must not** contain a **fractional** part
- **No** silent promotion/demotion
- **Conversion** can be used

```
type Counter_T is range 0 .. 40_000; -- integer type
OK : Counter_T := 0; -- Right type, legal
Bad : Counter_T := 0.0 ; -- Promotion, compile error
Legal : Counter_T := Counter_T (0.0); -- Conversion, legal
```

String Attributes For All Scalars

- `T'Image( input )`
  - Converts `T` → `String`
- `T'Value( input )`
  - Converts `String` → `T`

```
Number : Integer := 12345;
Input  : String( 1 .. N );
...
Put_Line( Integer'Image(Number) );
...
Get( Input );
Number := Integer'Value( Input );
```

Range Attributes For All Scalars

- `T'First`
  - First (**smallest**) value of type `T`
- `T'Last`
  - Last (**greatest**) value of type `T`
- `T'Range`
  - Shorthand for `T'First .. T'Last`

```
type Signed_T is range -99 .. 100;
Smallest : Signed_T := Signed_T'First; -- -99
Largest  : Signed_T := Signed_T'Last;  -- 100
```

Neighbor Attributes For All Scalars

- `T'Pred (Input)`
  - Predecessor of specified value
  - Input type must be `T`
- `T'Succ (Input)`
  - Successor of specified value
  - Input type must be `T`

```
type Signed_T is range -128 .. 127;
type Unsigned_T is mod 256;
Signed   : Signed_T := -1;
Unsigned : Unsigned_T := 0;
...
Signed := Signed_T'Succ( Signed ); -- Signed = 0
...
Unsigned := Unsigned_T'Pred( Unsigned ); -- Signed = 255
```

Min/Max Attributes For All Scalars

- `T'Min (Value_A, Value_B)`
  - **Lesser** of two `T`
- `T'Max (Value_A, Value_B)`
  - **Greater** of two `T`

```
Safe_Lower : constant := 10;
Safe_Upper : constant := 30;
C : Integer := 15;
...
C := Integer'Max (Safe_Lower, C - 1);
...
C := Integer'Min (Safe_Upper, C + 1);
```

Quiz

What happens when you try to compile/run this code?

```
C1 : constant := 2 ** 1024;
C2 : constant := 2 ** 1024 + 10;
C3 : constant := C1 - C2;
V  : Integer := C1 - C2;
```

A. Compile error
B. Run-time error
C. V is assigned to -10
D. Unknown - depends on the compiler

Quiz

What happens when you try to compile/run this code?

```
C1 : constant := 2 ** 1024;
C2 : constant := 2 ** 1024 + 10;
C3 : constant := C1 - C2;
V  : Integer := C1 - C2;
```

A. Compile error
B. Run-time error
C. ***V is assigned to -10***
D. Unknown - depends on the compiler

Explanations

- 2^{1024} too big for most run-times BUT
- `C1`, `C2`, and `C3` are named numbers, not typed constants
  - Compiler uses unbounded precision for named numbers
  - Large intermediate representation does not get stored in object code
- For assignment to `V`, subtraction is computed by compiler
  - `V` is assigned the value -10

Enumeration Types

Examples

```
with Ada.Text_IO; use Ada.Text_IO;
procedure Discrete_Enumeration_Types is

   type Colors_Type is (Red, Orange, Yellow, Green, Blue, Indigo, Violet);
   Color : Colors_Type := Red;

   type Traffic_Light_Type is (Red, Yellow, Green);
   for Traffic_Light_Type use (1, 2, 4);
   Stoplight : Traffic_Light_Type := Red;

   type Roman_Numeral_Digit_Type is ('I', 'V', 'X', 'L', 'C', 'M');
   Digit : Roman_Numeral_Digit_Type := 'I';

   Flag : Boolean;

   Position : Integer;

begin

   Position  := Traffic_Light_Type'Pos (Green);
   Color     := Colors_Type'Val (Position);
   Stoplight := Traffic_Light_Type'(Red);
   Digit     := Roman_Numeral_Digit_Type'Succ (Digit);
   Flag      := End_Of_Line;

   Put_Line (Position'Image);
   Put_Line (Color'Image);
   Put_Line (Flag'Image);
   Put_Line (Digit'Image);
   Put_Line (Stoplight'Image);

end Discrete_Enumeration_Types;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/030_basic_types.html#discrete-enumeration-types

Enumeration Types

- Enumeration of **logical** values
  - Integer value is an implementation detail
- Syntax

```
type <identifier> is ( <identifier-list> ) ;
```

- Literals
  - Distinct, ordered
  - Can be in **multiple** enumerations

```
type Colors is (Red, Orange, Yellow, Green, Blue, Violet);
type Stop_Light is (Red, Yellow, Green);
...
-- Red both a member of Colors and Stop_Light
Shade : Colors := Red;
Light : Stop_Light := Red;
```

Enumeration Type Operations

- Assignment, relationals
- **Not** numeric quantities
  - *Possible* with attributes
  - Not recommended

```
type Directions is ( North, South, East, West );
type Days is ( Mon, Tue, Wed, Thu, Fri, Sat, Sun );
Heading : Directions;
Today, Tomorrow : Days;
...
Today := Mon;
Today := North; -- compile error
Heading := South;
Heading := East + 1; -- compile error
if Today < Tomorrow then ...
```

Character Types

- Literals
  - Enclosed in single quotes eg. `'A'`
  - Case-sensitive
- **Special-case** of enumerated type
  - At least one character enumeral
- System-defined `Character`
- Can be user-defined

```
type EBCDIC is ( nul, ..., 'a' , ..., 'A', ..., del );
Control : EBCDIC := 'A';
Nullo : EBCDIC := nul;
```

Language-Defined Type Boolean

- Enumeration

```
type Boolean is ( False, True );
```

- Supports assignment, relational operators, attributes

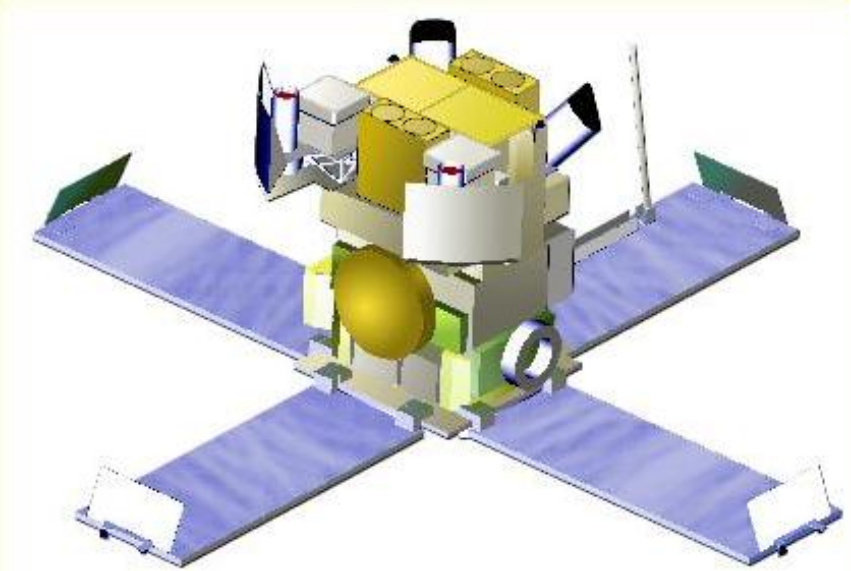
```
A : Boolean;
Counter : Integer;
...
A := (Counter = 22);
```

- Logical operators **and**, **or**, **xor**, **not**

```
A := B or ( not C ); -- For A, B, C boolean
```

Why Boolean Isn't Just An Integer?

- Example: Real-life error
  - HETE-2 satellite **attitude control** system software (ACS)
  - Written in **C**
- Controls four "solar paddles"
  - Deployed after launch



Why Boolean Isn't Just An Integer!

- **Initially** variable with paddles' state
  - Either **all** deployed, or **none** deployed
- Used `int` as a boolean

```
if (rom->paddles_deployed == 1)
  use_deployed_inertia_matrix();
else
  use_stowed_inertia_matrix();
```

- Later `paddles_deployed` became a **4-bits** value
  - One bit per paddle
  - `0` → none deployed, `0xF` → all deployed
- Then, `use_deployed_inertia_matrix()` if only first paddle is deployed!
- Better: boolean function `paddles_deployed()`
  - Single line to modify

Boolean Operators' Operand Evaluation

- Evaluation order **not specified**
- May be needed
  - Checking value **before** operation
  - Dereferencing null pointers
  - Division by zero

```
if Divisor /= 0 and K / Divisor = Max then ... -- Problem!
```

Short-Circuit Control Forms

- **Short-circuit** → **fixed** evaluation order
- Left-to-right
- Right only evaluated **if necessary**
  - `and then`: if left is `False`, skip right

    ```
    Divisor /= 0 and then K / Divisor = Max
    ```

  - `or else`: if left is `True`, skip right

    ```
    Divisor = 0 or else K / Divisor = Max
    ```

Quiz

```
type Enum_T is ( Able, Baker, Charlie );
```

Which statement will generate an error?

A. `V1 : Enum_T := Enum_T'Value ("Able");`
B. `V2 : Enum_T := Enum_T'Value ("BAKER");`
C. `V3 : Enum_T := Enum_T'Value (" charlie ");`
D. `V4 : Enum_T := Enum_T'Value ("Able Baker Charlie");`

Quiz

```
type Enum_T is ( Able, Baker, Charlie );
```

Which statement will generate an error?

A. `V1 : Enum_T := Enum_T'Value ("Able");`
B. `V2 : Enum_T := Enum_T'Value ("BAKER");`
C. `V3 : Enum_T := Enum_T'Value (" charlie ");`
D. *`V4 : Enum_T := Enum_T'Value ("Able Baker Charlie");`*

Explanations

A. Legal
B. Legal - conversion is case-insensitive
C. Legal - leading/trailing blanks are ignored
D. `Value` tries to convert entire string, which will fail at run-time

Real Types

Examples

```
with Ada.Text_IO; use Ada.Text_IO;
procedure Real_Types is

   Predefined_Floating_Point : constant Float := 0.0;

   type Floating_Point_Type is digits 8 range -1.0e10 .. 1.0e10;
   Floating_Point : Floating_Point_Type := 1.234e2;

begin

   Put_Line (Integer'Image (Floating_Point_Type'Digits));
   Put_Line (Integer'Image (Floating_Point_Type'Base'Digits));
   Floating_Point := Floating_Point_Type'Succ (Floating_Point);
   Put_Line (Floating_Point_Type'Image (Floating_Point));
   Put_Line (Predefined_Floating_Point'Image);

end Real_Types;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/030_basic_types.html#real-types

Real Types

- Approximations to **continuous** values
  - 1.0, 1.1, 1.11, 1.111 ... 2.0, ...
  - Finite hardware $\rightarrow$ approximations
- Floating-point
  - **Variable** exponent
  - **Large** range
  - Constant **relative** precision
- Fixed-point
  - **Constant** exponent
  - **Limited** range
  - Constant **absolute** precision
  - Subdivided into Binary and Decimal
- Class focuses on floating-point

Real Type (Floating and Fixed) Literals

- **Must** contain a fractional part
- No silent promotion

```
type Phase is digits 8; -- floating-point
OK : Phase := 0.0;
Bad : Phase := 0 ; -- compile error
```

Declaring Floating Point Types

- Syntax

```
type <identifier> is
    digits <expression> [range constraint];
```

  - *digits* → **minimum** number of significant digits
  - **Decimal** digits, not bits

- Compiler choses representation
  - From **available** floating point types
  - May be **more** accurate, but not less
  - If none available → declaration is **rejected**

Predefined Floating Point Types

- Type `Float` >= 6 digits
- Additional implementation-defined types
  - `Long_Float` >= 11 digits
- General-purpose
- Best to **avoid** predefined types
  - Loss of **portability**
  - Easy to avoid

Floating Point Type Operators

- By increasing precedence

  relational operator `=` | `/=` | `<` | `>=` | `>` | `>=`

  binary adding operator `+` | `-`

  unary adding operator `+` | `-`

  multiplying operator `*` | `/`

  highest precedence operator `**` | `abs`

- *Note* on floating-point exponentiation `**`
  - Power must be `Integer`
    - Not possible to ask for root
    - `X**0.5` → `sqrt(x)`

Floating Point Type Attributes

- *Core* attributes

```
type Real is digits N;   -- N static
```

  - `Real'Digits`
    - Number of digits **requested** (N)
  - `Real'Base'Digits`
    - Number of **actual** digits
  - `Real'Rounding (X)`
    - Integral value nearest to `X`
    - *Note* `Float'Rounding (0.5) = 1` and `Float'Rounding (-0.5) = -1`

- Model-oriented attributes
  - Advanced machine representation of the floating-point type
  - Mantissa, strict mode

Numeric Types Conversion

- Ada's integer and real are *numeric*
  - Holding a numeric value
- Special rule: can always convert between numeric types
  - Explicitly
  - `Real` → `Integer` causes **rounding**

```
declare
   N : Integer := 0;
   F : Float := 1.5;
begin
   N := Integer (F); -- N = 2
   F := Float (N); -- F = 2.0
```

Quiz

What is the output of this code?

```
declare
   F : Float := 7.6;
   I : Integer := 10;
begin
   F := Float ( Integer(F) / I );
   Put_Line ( Float'Image ( F ) );
end;
```

A. 7.6
B. Compile Error
C. 8.0
D. 0.0

Quiz

What is the output of this code?

```
declare
   F : Float := 7.6;
   I : Integer := 10;
begin
   F := Float ( Integer(F) / I );
   Put_Line ( Float'Image ( F ) );
end;
```

A. 7.6
B. Compile Error
C. 8.0
D. ***0.0***

Explanations

A. Result of `F := F / Float(I);`
B. Result of `F := F / I;`
C. Result of `F := Float (Integer (F)) / Float (I);`
D. Integer value of `F` is 8. Integer result of dividing that by 10 is 0. Converting to float still gives us 0

Miscellaneous

Checked Type Conversions

- Between "closely related" types
  - Numeric types
  - Inherited types
  - Array types
- Illegal conversions **rejected**
  - Unsafe **Unchecked_Conversion** available
- Functional syntax
  - Function named `Target_Type`
  - Implicitly defined
  - **Must** be explicitly called

```
Target_Float := Float (Source_Integer);
```

Default Value

Ada 2012

- Not defined by language for **scalars**
- Can be done with an **aspect clause**
  - Only during type declarations
  - <value> must be static

```
type Type_Name is <type_definition>
     with Default_Value => <value>;
```

- Example

```
type Tertiary_Switch is (Off, On, Neither)
   with Default_Value => Neither;
Implicit : Tertiary_Switch; -- Implicit = Neither
Explicit : Tertiary_Switch := Neither;
```

Simple Static Type Derivation

- New type from an existing type
  - **Limited** form of inheritance: operations
  - **Not** fully OOP
  - More details later
- Strong type benefits
  - Only **explicit** conversion possible
  - eg. `Meters` can't be set from a `Feet` value
- Syntax

```
type identifier is new Base_Type [<constraints>]
```

- Example

```
type Measurement is digits 6;
type Distance is new Measurement
      range 0.0 .. Measurement'Last;
```

Subtypes

Examples

```
with Ada.Text_IO; use Ada.Text_IO;
procedure Subtypes is
   type Days_T is (Sun, Mon, Tues, Wed, Thurs, Fri, Sat);
   subtype Weekdays_T is Days_T range Mon .. Fri;

   Weekday      : Weekdays_T              := Mon;
   Also_Weekday : Days_T range Mon .. Fri := Tues;
   Day          : Days_T                  := Weekday;

   type Matrix_T is array (Integer range <>, Integer range <>) of Integer;
   subtype Matrix_3x3_T is Matrix_T (1 .. 3, 1 .. 3);
   subtype Line_T is String (1 .. 80);

   I : Integer := 1_234;
   procedure Takes_Positive (P : Positive) is null;

   type Tertiary_Switch is (Off, On, Neither) with
      Default_Value => Neither;
   subtype Toggle_Switch is Tertiary_Switch range Off .. On;
   Safe : Toggle_Switch := Off;
   -- Implicit : Toggle_Switch; -- compile error: out of range

   pragma Unreferenced (Safe);

begin
   Also_Weekday := Day;  -- runtime error if Day is Sat or Sun
   Put_Line (Also_Weekday'Image);
   Day := Weekday;  -- always legal
   I   := I - 1;
   Takes_Positive (I); -- runtime error if I <= 0

   Weekday := Weekdays_T'Last;
   Day     := Days_T'Last;

   Put_Line (Weekdays_T'Image (Weekday) & " / " & Days_T'Image (Day));
   Put_Line (Days_T'Image (Weekdays_T'Succ (Weekday)));
   Put_Line (Integer'Image (Matrix_3x3_T'Length (1)));
   Put_Line (Integer'Image (Line_T'Length (1)));
end Subtypes;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/080_expressions.html#subtypes

Subtype

- May **constrain** an existing type
- Still the **same** type
- Syntax

```
subtype Defining_Identifier is Type_Name [constraints];
```

  - `Type_Name` is an existing `type` or `subtype`
- If no constraint → type alias

Subtype Example

- Enumeration type with **range** constraint

```
type Days is (Sun, Mon, Tues, Wed, Thurs, Fri, Sat);
subtype Weekdays is Days range Mon .. Fri;
Workday : Weekdays; -- type Days limited to Mon .. Fri
```

- Equivalent to **anonymous** subtype

```
Same_As_Workday : Days range Mon .. Fri;
```

Kinds of Constraints

- Range constraints on discrete types

```
subtype Positive is Integer range 1 .. Integer'Last;
subtype Natural is Integer range 0 .. Integer'Last;
subtype Weekdays is Days range Mon .. Fri;
subtype Symmetric_Distribution is
    Float range -1.0 .. +1.0;
```

- Other kinds, discussed later

Effects of Constraints

- Constraints only on values

```
type Days is (Mon, Tue, Wed, Thu, Fri, Sat, Sun);
subtype Weekdays is Days range Mon .. Fri;
subtype Weekend is Days range Sat .. Sun;
```

- Functionalities are **kept**

```
subtype Positive is Integer range 1 .. Integer'Last;
P : Positive;
X : Integer := P; -- X and P are the same type
```

Assignment Respects Constraints

- RHS values must satisfy type constraints
- `Constraint_Error` otherwise

```
Q : Integer  := some_value;
P : Positive := Q; -- runtime error if Q <= 0
N : Natural  := Q; -- runtime error if Q < 0
J : Integer  := P; -- always legal
K : Integer  := N; -- always legal
```

Range Constraint Examples

```
subtype Proper_Subset is Positive range 1 .. 10;
subtype Same_Constraints is Positive
    range 1 .. Integer'Last;
subtype Letter is Character range 'A' .. 'z';
subtype Upper_Case is Letter range 'A' .. 'Z';
subtype Lower_Case is Letter range 'a' .. 'z';
subtype Null_Range is Integer
    range 1 .. 0;  -- silly when hard-coded...
-- evaluated when subtype defined, not when object declared
subtype Dynamic is Integer range Lower .. Upper;
```

Quiz

```
type Enum_T is (Sat, Sun, Mon, Tue, Wed, Thu, Fri);
subtype Enum_Sub_T is Enum_T range Mon .. Fri;
```

Which subtype definition is valid?

A. `subtype A is Enum_Sub_T range Enum_Sub_T'Pred (Enum_Sub_T'First) .. Enum_Sub_T'Last;`
B. `subtype B is range Sat .. Mon;`
C. `subtype C is Integer;`
D. `subtype D is digits 6;`

Quiz

```
type Enum_T is (Sat, Sun, Mon, Tue, Wed, Thu, Fri);
subtype Enum_Sub_T is Enum_T range Mon .. Fri;
```

Which subtype definition is valid?

A. `subtype A is Enum_Sub_T range Enum_Sub_T'Pred (Enum_Sub_T'First) .. Enum_Sub_T'Last;`
B. `subtype B is range Sat .. Mon;`
C. *`subtype C is Integer;`*
D. `subtype D is digits 6;`

Explanations

A. This generates a run-time error because the first enumeral specified is not in the range of `Enum_Sub_T`
B. Compile error - no type specified
C. Correct - standalone subtype
D. `Digits 6` is used for a type definition, not a subtype

Lab

Basic Types Lab

- Create types to handle the following concepts
  - Determining average test score
    - Number of tests taken
    - Total of all test scores
  - Number of degrees in a circle
  - Collection of colors
- Create objects for the types you've created
  - Assign initial values to the objects
  - Print the values of the objects
- Modify the objects you've created and print the new values
  - Determine the average score for all the tests
  - Add 359 degrees to the initial circle value
  - Set the color object to the value right before the last possible value

Basic Types Lab Hints

- Understand the properties of the types
  - Do you need fractions or just whole numbers?
  - What happens when you want the number to wrap?
- Predefined package **Ada.Text_IO** is handy...
  - Procedure **Put_Line** takes a **String** as the parameter
- Remember attribute **'Image** returns a **String**

```
<typemark>'Image ( Object )
Object'Image
```

Basic Types Lab Solution - Declarations

```
with Ada.Text_IO; use Ada.Text_IO;
procedure Main is

   type Number_Of_Tests_T is range 0 .. 100;
   type Test_Score_Total_T is digits 6 range 0.0 .. 10_000.0;

   type Degrees_T is mod 360;

   type Cymk_T is (Cyan, Magenta, Yellow, Black);

   Number_Of_Tests  : Number_Of_Tests_T;
   Test_Score_Total : Test_Score_Total_T;

   Angle : Degrees_T;

   Color : Cymk_T;
```

Basic Types Lab Solution - Implementation

```
begin

   -- assignment
   Number_Of_Tests  := 15;
   Test_Score_Total := 1_234.5;
   Angle            := 180;
   Color            := Magenta;

   Put_Line (Number_Of_Tests'Image);
   Put_Line (Test_Score_Total'Image);
   Put_Line (Angle'Image);
   Put_Line (Color'Image);

   -- operations / attributes
   Test_Score_Total := Test_Score_Total / Test_Score_Total_T (Number_Of_Tests);
   Angle            := Angle + 359;
   Color            := Cymk_T'Pred (Cymk_T'Last);

   Put_Line (Test_Score_Total'Image);
   Put_Line (Angle'Image);
   Put_Line (Color'Image);

end Main;
```

Basic Types Extra Credit

- See what happens when your data is invalid / illegal
  - Number of tests = 0
  - Assign a very large number to the test score total
  - Color type only has one value
  - Add a number larger than 360 to the circle value

Summary

Benefits of Strongly Typed Numerics

- **Prevent** subtle bugs
- Cannot mix `Apples` and `Oranges`
- Force to clarify **representation** needs
  - eg. constant with or with fractional part

```
type Yen is range 0 .. 1_000_000;
type Ruble is range 0 .. 1_000_000;
Mine : Yen := 1;
Yours : Ruble := 1;
Mine := Yours; -- illegal
```

User-Defined Numeric Type Benefits

- Close to **requirements**
  - Types with **explicit** requirements (range, precision, etc.)
  - Best case: Incorrect state **not possible**
- Either implemented/respected or rejected
  - No run-time (bad) suprise
- **Portability** enhanced
  - Reduced hardware dependencies

Summary

- User-defined types and strong typing is **good**
  - Programs written in application's terms
  - Computer in charge of checking constraints
  - Security, reliability requirements have a price
  - Performance **identical**, given **same requirements**
- User definitions from existing types *can* be good
- Right **trade-off** depends on **use-case**
  - More types → more precision → less bugs
  - Storing **both** feet and meters in `Float` has caused bugs
  - More types → more complexity → more bugs
  - A `Green_Round_Object_Altitude` type is probably **never needed**
- Default initialization is **possible**
  - Use **sparingly**

Statements

Introduction

Statement Kinds

```
simple_statement ::=
  null | assignment | exit |
  goto | delay | raise |
  procedure_call | return |
  requeue | entry_call |
  abort | code

compound_statement ::=
  if | case | loop |
  block | accept | select
```

Procedure Calls (Overview)

- Procedure calls are statements as shown here
- More details in "Subprograms" section

```
procedure Activate ( This : in out Foo; Wait : in Boolean);
```

- Traditional call notation

```
Activate (Idle, True);
```

- "Distinguished Receiver" notation
  - For `tagged` types

```
Idle.Activate (True);
```

Parameter Associations In Calls

- Traditional *positional association* is allowed
  - Nth actual parameter goes to nth formal parameter

```
Activate ( Idle, True ); -- positional
```

- *Named association* also allowed
  - Name of formal parameter is explicit

```
Activate ( This => Idle, Wait => True ); -- named
```

- Both can be used together

```
Activate ( Idle, Wait => True ); -- named then positional
```

- But positional following named is a compile error

```
Activate ( This => Idle, True ); -- ERROR
```

Block Statements

Block Statements

- Local **scope**
- Optional declarative part
- Used for
  - Temporary declarations
  - Declarations as part of statement sequence
  - Local catching of exceptions
- Syntax

```
[block-name :]
[declare <declarative part> ]
begin
   <statements>
end [block-name];
```

Block Statements Example

```
begin
   Get (V);
   Get (U);
   if U > V then -- swap them
      Swap: declare
         Temp : Integer;
      begin
         Temp := U;
         U := V;
         V := Temp;
      end Swap;
      -- Temp does not exist here
   end if;
   Print (U);
   Print (V);
end;
```

Null Statements

Null Statements

- Explicit no-op statement
- Constructs with required statement
- Explicit statements help compiler
  - Oversights
  - Editing accidents

```
case Today is
  when Monday .. Thursday =>
    Work (9.0);
  when Friday =>
    Work (4.0);
  when Saturday .. Sunday =>
    null;
end case;
```

Assignment Statements

Examples

```
with Ada.Text_IO; use Ada.Text_IO;
procedure Assignment_Statements is

   Max_Miles : constant Integer := 20;

   type Feet_T is range 0 .. Max_Miles * 5_280;
   type Miles_T is range 0 .. Max_Miles;

   Feet  : constant Feet_T := Feet_T (Line) * 1_000;
   Miles : Miles_T         := 0;

   Index1, Index2 : Miles_T range 1 .. 20;

begin

   -- Miles := Feet / 5_280; -- compile error

   -- Max_Miles := Max_Miles + 1; -- compile error

   Index1 := Miles_T (Max_Miles); -- constraint checking added
   Index2 := Index1;     -- no constraint checking needed

   Put_Line ("Index1 = " & Index1'Image);
   Put_Line ("Index2 = " & Index2'Image);

   Index1 := 0; -- run-time error
   Put_Line ("Index1 = " & Index1'Image);

end Assignment_Statements;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/040_statements.html#assignment-statements

Assignment Statements

- Syntax

  `<variable> := <expression>;`

- Value of expression is copied to target variable
- The type of the RHS must be same as the LHS
  - Rejected at compile-time otherwise

```
type Miles_T is range 0 .. Max_Miles;
type Km_T is range 0 .. Max_Kilometers
...
M : Miles_T := 2; -- universal integer legal for any integer
K : Km_T := 2; -- universal integer legal for any integer
M := K; -- compile error
```

Assignment Statements, Not Expressions

- Separate from expressions
  - No Ada equivalent for these:

```
int a = b = c = 1;
while (line = readline(file))
   { ...do something with line... }
```

- No assignment in conditionals
  - E.g. `if ( a == 1 )` compared to `if ( a = 1 )`

Assignable Views

- A *view* controls the way an entity can be treated
  - At different points in the program text
- The named entity must be an assignable variable
  - Thus the view of the target object must allow assignment
- Various un-assignable views
  - Constants
  - Variables of `limited` types
  - Formal parameters of mode `in`

```
Max : constant Integer := 100;
...
Max := 200; -- illegal
```

Target Variable Constraint Violations

- Prevent update to target value
  - Target is not changed at all
- May compile but will raise error at runtime
  - Predefined exception `Constraint_Error` is raised
- May be detected by compiler
  - Static value
  - Value is outside base range of type

```
Max : Integer range 1 .. 100 := 100;
...
Max := 0; -- run-time error
```

Implicit Range Constraint Checking

- The following code

```
procedure Demo is
  K : Integer;
  P : Integer range 0 .. 100;
begin
  ...
  P := K;
  ...
end Demo;
```

- Generates assignment checks similar to

```
if K < 0 or K > 100 then
  raise Constraint_Error;
else
  P := K;
end if;
```

- Run-time performance impact

Not All Assignments Are Checked

- Compilers assume variables of a subtype have appropriate values
- No check generated in this code

```
procedure Demo is
   P, K : Integer range 0 .. 100;
begin
   ...
   P := K;
   ...
end Demo;
```

Quiz

```
type One_T is range 0 .. 100;
type Two_T is range 0 .. 100;
A : constant := 100;
B : constant One_T := 99;
C : constant Two_T := 98;
X : One_T := 0;
Y : Two_T := 0;
```

Which block is illegal?

A.
```
X := A;
Y := A;
```

B.
```
X := B;
Y := C;
```

C.
```
X := One_T(X + C);
```

D.
```
X := One_T(Y);
Y := Two_T(X);
```

Quiz

```
type One_T is range 0 .. 100;
type Two_T is range 0 .. 100;
A : constant := 100;
B : constant One_T := 99;
C : constant Two_T := 98;
X : One_T := 0;
Y : Two_T := 0;
```

Which block is illegal?

A.
```
X := A;
Y := A;
```

B.
```
X := B;
Y := C;
```

C.
```
X := One_T(X + C);
```

D.
```
X := One_T(Y);
Y := Two_T(X);
```

Explanations

A. Legal - `A` is an untyped constant
B. Legal - `B`, `C` are correctly typed
C. Illegal - C must be cast by itself
D. Legal - Values are typecast appropriately

Conditional Statements

Examples

```
with Ada.Text_IO; use Ada.Text_IO;
procedure Conditional_Statements is
   type Light_T is (Red, Yellow, Green);
   A, B  : Integer          := Integer (Line);
   Speed : Integer;
   Light : constant Light_T := Light_T'Val (Line);

begin
   if Light = Red then
      Speed := 0;
   elsif Light = Green then
      Speed := 25;
   else
      Speed := 50;
   end if;

   case Light is
      when Red =>    Speed := 0;
      when Green =>  Speed := 25;
      when Yellow => Speed := 50;
   end case;

   case A is
      when 1 .. 100   => B := A;
      when -100 .. -1 => B := -A;
      when others     => A := B;
   end case;

   Put_Line ("Speed = " & Speed'Image);
   Put_Line ("Light = " & Light'Image);

end Conditional_Statements;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/040_statements.html#conditional-statements

If-then-else Statements

- Control flow using Boolean expressions
- Syntax

```
if <boolean expression> then -- No parentheses
   <statements>;
[else
   <statements>;]
end if;
```

- At least one statement must be supplied
  - `null` for explicit no-op

If-then-elsif Statements

- Sequential choice with alternatives
- Avoids `if` nesting
- `elsif` alternatives, tested in textual order
- `else` part still optional

```
1  if Valve(N) /= Closed then
2    Isolate (Valve(N));
3    Failure (Valve (N));
4  else
5    if System = Off then
6      Failure (Valve (N));
7    end if;
8  end if;
```

```
1  if Valve(N) /= Closed then
2    Isolate (Valve(N));
3    Failure (Valve (N));
4  elsif System = Off then
5    Failure (Valve (N));
6  end if;
```

Case Statements

- Exclusionary choice among alternatives
- Syntax

```
case <expression> is
  when <choice> => <statements>;
  { when <choice> => <statements>; }
end case;
```

```
choice ::= <expression> | <discrete range>
         | others { "|" <other choice> }
```

Simple case Statements

```
type Directions is  (Forward, Backward, Left, Right);
Direction : Directions;
...
case Direction is
  when Forward =>  Go_Forward (1);
  when Backward => Go_Backward (1);
  when Left =>  Go_Left (1);
  when Right => Go_Right (1);
end case;
```

- *Note*: No fall-through between cases

Case Statement Rules

- More constrained than a if-elsif structure
- **All** possible values must be covered
  - Explicitly
  - ... or with `others` keyword
- Choice values cannot be given more than once (exclusive)
  - Must be known at **compile** time

Others Choice

- Choice by default
  - "everything not specified so far"
- Must be in last position

```
case Today is    -- work schedule
  when Monday =>
    Go_To (Work, Arrive=>Late, Leave=>Early);
  when Tuesday | Wednesday | Thursday => -- Several choices
    Go_To (Work, Arrive=>Early, Leave=>Late);
  when Friday =>
    Go_To (Work, Arrive=>Early, Leave=>Early);
  when others => -- weekend
    Go_To (Home, Arrive=>Day_Before, Leave=>Day_After);
end case;
```

Case Statements Range Alternatives

```
case Altitude_Ft is
  when 0 .. 9 =>
    Set_Flight_Indicator (Ground);
  when 10 .. 40_000 =>
    Set_Flight_Indicator (In_The_Air);
  when others => -- Large altitude
    Set_Flight_Indicator (Too_High);
end case;
```

Dangers of *Others* Case Alternative

- Maintenance issue: new value requiring a new alternative?
  - Compiler won't warn: `others` hides it

```
type Agencies_T is (NASA, ESA, RFSA); -- could easily grow
Bureau : Agencies_T;
...
case Bureau is
   when ESA =>
      Set_Region (Europe);
   when NASA =>
      Set_Region (America);
   when others =>
      Set_Region (Russia); -- New agencies will be Russian!
end case;
```

Quiz

```
A : integer := 100;
B : integer := 200;
```

Which choice needs to be modified to make a valid `if` block

A.
```
if A == B and then A != 0 then
   A := Integer'First;
   B := Integer'Last;
```

B.
```
elsif A < B then
   A := B + 1;
```

C.
```
elsif A > B then
   B := A - 1;
```

D.
```
end if;
```

Quiz

```
A : integer := 100;
B : integer := 200;
```

Which choice needs to be modified to make a valid `if` block

A.
```
if A == B and then A != 0 then
   A := Integer'First;
   B := Integer'Last;
```

B.
```
elsif A < B then
   A := B + 1;
```

C.
```
elsif A > B then
   B := A - 1;
```

D.
```
end if;
```

Explanations

- A uses the C-style equality/inequality operators
- D is legal because `else` is not required

Quiz

```
type Enum_T is (Sun, Mon, Tue, Wed, Thu, Fri, Sat);
A : Enum_T;
```

Which choice needs to be modified to make a valid `case` block

```
case A is
```

A.
```
when Sun =>
   Put_Line ( "Day Off" );
```

B.
```
when Mon | Fri =>
   Put_Line ( "Short Day" );
```

C.
```
when Tue .. Thu =>
   Put_Line ( "Long Day" );
```

D.
```
end case;
```

Quiz

```
type Enum_T is (Sun, Mon, Tue, Wed, Thu, Fri, Sat);
A : Enum_T;
```

Which choice needs to be modified to make a valid `case` block

```
case A is
```

A.
```
when Sun =>
   Put_Line ( "Day Off" );
```

B.
```
when Mon | Fri =>
   Put_Line ( "Short Day" );
```

C.
```
when Tue .. Thu =>
   Put_Line ( "Long Day" );
```

D.
```
end case;
```

Explanations

- Ada requires all possibilities to be covered
- Add `when others` or `when Sat`

Loop Statements

Examples

```
with Ada.Text_IO; use Ada.Text_IO;
procedure Loop_Statements is
   File    : File_Type;
   Counter : Integer := 0;
   type Light_T is (Red, Yellow, Green);
begin
   loop
      if not Is_Open (File) then
         exit;
      end if;
      Counter := Counter + 1;
      exit when Is_Open (File);
   end loop;

   while Is_Open (File) loop
      Counter := Counter - 1;
   end loop;

   for Light in Light_T loop
      Put_Line (Light_T'Image (Light));
   end loop;

   for Counter in reverse 1 .. 10 loop
      Put_Line (Integer'Image (Counter));
      exit when Is_Open (File);
   end loop;
end Loop_Statements;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/040_statements.html#loop-statements

Basic Loops and Syntax

- All kind of loops can be expressed
  - Optional iteration controls
  - Optional exit statements
- Syntax

```
[<name> :] [iteration_scheme] loop
      <statements>
 end loop [<name>];

iteration_scheme ::= while <boolean expression>
                   | for <loop_parameter_specification>
                   | for <loop_iterator_specification>
```

- Example

```
Wash_Hair : loop
  Lather (Hair);
  Rinse (Hair);
end loop Wash_Hair;
```

Loop Exit Statements

- Leaves innermost loop
  - Unless loop name is specified
- Syntax

  ```
  exit [<loop name>] [when <boolean expression>];
  ```

- `exit when` exits with condition

```
loop
   ...
   -- If it's time to go then exit
   exit when Time_to_Go;
   ...
end loop;
```

Exit Statement Examples

- Equivalent to C's `do while`

```
loop
   Do_Something;
   exit when Finished;
end loop;
```

- Nested named loops and exit

```
Outer : loop
   Do_Something;
   Inner : loop
      ...
      exit Outer when Finished; -- will exit all the way out
      ...
   end loop Inner;
end loop Outer;
```

While-loop Statements

- Syntax

```
while boolean_expression loop
   sequence_of_statements
end loop;
```

- Identical to

```
loop
   exit when not boolean_expression;
   sequence_of_statements
end loop;
```

- Example

```
while Count < Largest loop
  Count := Count + 2;
  Display (Count);
end loop;
```

For-loop Statements

- One low-level form
  - General-purpose (looping, array indexing, etc.)
  - Explicitly specified sequences of values
  - Precise control over sequence
- Two high-level forms
  - Ada 2012
  - Focused on objects
  - Seen later with Arrays

For in Statements

- Successive values of a **discrete** type
  - eg. enumerations values
- Syntax

```
for name in [reverse] discrete_subtype_definition loop
...
end loop;
```

- Example

```
for Day in Days_T loop
   Refresh_Planning (Day);
end loop;
```

Variable and Sequence of Values

- Variable declared implicitly by loop statement
  - Has a view as constant
  - No assignment or update possible
- Initialized as `'First`, incremented as `'Succ`
- Syntaxic sugar: several forms allowed

```
-- All values of a type or subtype
for Day in Days_T loop
for Day in Days_T range Mon .. Fri -- anonymous subtype
-- Constant and variable range
for Day in Mon .. Fri loop
Today, Tomorrow : Days_T;
...
for Day in Today .. Tomorrow loop
```

Low-Level For-loop Parameter Type

- The type can be implicit
  - As long as it is clear for the compiler
  - Warning: same name can belong to several enums

```
-- Error if Red and Green in Color_T and Stoplight_T
for Color in Red .. Green loop
```

- Type **Integer** by default
  - Each bound must be a **universal_integer**

Null Ranges

- *Null range* when lower bound > upper bound
  - `1 .. 0`, `Fri .. Mon`
  - Literals and variables can specify null ranges
- No iteration at all (not even one)
- Shortcut for upper bound validation

```
-- Null range: loop not entered
for Today in Fri .. Mon loop
```

Reversing Low-Level Iteration Direction

- Keyword **reverse** reverses iteration values
  - Range must still be ascending
  - Null range still cause no iteration

```
for This_Day in reverse Mon .. Fri loop
```

For-Loop Parameter Visibility

- Scope rules don't change
- Inner objects can hide outer objects

```
Block: declare
   Counter : Float := 0.0;
begin
   -- For_Loop.Counter hides Block.Counter
   For_Loop : for Counter in Integer range A .. B loop
   ...
   end loop;
end;
```

Referencing Hidden Names

- Must copy for-loop parameter to some other object if needed after the loop exits
- Use dot notation with outer scope name when hiding occurs

```
Foo:
declare
   Counter : Float := 0.0;
begin
   ...
   for Counter in Integer range 1 .. Number_Read loop
      -- set declared "Counter" to loop counter
      Foo.Counter := Float (Counter);
      ...
   end loop;
   ...
end Foo;
```

Iterations Exit Statements

- Early loop exit
- Syntax

```
exit [<loop_name>] [when <condition>]
```

- No name: Loop exited **entirely**
  - Not only current iteration

```
for K in 1 .. 1000 loop
   exit when K > F(K);
end loop;
```

- With name: Specified loop exited

```
for J in 1 .. 1000 loop
    Inner: for K in 1 .. 1000 loop
       exit Inner when K > F(K);
    end loop;
end loop;
```

For-Loop with Exit Statement Example

```
-- find position of Key within Table
Found := False;
-- iterate over Table
Search : for Index in Table'Range loop
  if Table(Index) = Key then
    Found := True;
    Position := Index;
    exit Search;
  elsif Table(Index) > Key then
    -- no point in continuing
    exit Search;
  end if;
end loop Search;
```

Quiz

```
A, B : Integer := 123;
```

Which loop block is illegal?

A.
```
for A in 1 ..  10 loop
   A := A + 1;
end loop;
```

B.
```
for B in 1 .. 10 loop
   Put_Line (Integer'Image (B));
end loop;
```

C.
```
for C in reverse 1 .. 10 loop
   Put_Line (Integer'Image (A));
end loop;
```

D.
```
for D in 10 .. 1 loop
   Put_Line (Integer'Image (D));
end loop;
```

.

Quiz

```
A, B : Integer := 123;
```

Which loop block is illegal?

A.
```
for A in 1 ..  10 loop
   A := A + 1;
end loop;
```

B.
```
for B in 1 .. 10 loop
   Put_Line (Integer'Image (B));
end loop;
```

C.
```
for C in reverse 1 .. 10 loop
   Put_Line (Integer'Image (A));
end loop;
```

D.
```
for D in 10 .. 1 loop
   Put_Line (Integer'Image (D));
end loop;
```

Explanations

A. Cannot assign to a loop parameter
B. Legal - 10 iterations
C. Legal - 10 iterations
D. Legal - 0 iterations

.

GOTO Statements

GOTO Statements

- Syntax

```
goto_statement ::= goto label;
label ::= << identifier >>
```

- Rationale
  - Historic usage
  - Arguably cleaner for some situations
- Restrictions
  - Based on common sense
  - Example: cannot jump into a **case** statement

GOTO Use

- Mostly discouraged
- May simplify control flow
- For example in-loop **continue** construct

```
loop
   -- lots of code
   ...
   goto continue;
   -- lots more code
   ...
   <<continue>>
end loop;
```

- As always maintainability beats hard set rules

Lab

Statements Lab

- Requirements
  - Create a simple algorithm to count number of hours worked in a week
    - Use **Ada.Text_IO.Get_Line** to ask user for hours worked on each day
    - Any hours over 8 gets counted as 1.5 times number of hours (e.g. 10 hours worked will get counted as 11 hours towards total)
    - Saturday hours get counted at 1.5 times number of hours
    - Sunday hours get counted at 2 times number of hours
  - Print total number of hours "worked"
- Hints
  - Use **for** loop to iterate over days of week
  - Use **if** statement to determine overtime hours
  - Use **case** statement to determine weekend bonus

Statements Lab Extra Credit

- Use an inner loop when getting hours worked to check validity
  - Less than 0 should exit outer loop
  - More than 24 should not be allowed

Statements Lab Solution

```
with Ada.Text_IO; use Ada.Text_IO;
procedure Main is
   type Days_Of_Week_T is
     (Sunday, Monday, Tuesday, Wednesday, Thursday, Friday, Saturday);
   type Hours_Worked is digits 6;

   Total_Worked : Hours_Worked := 0.0;
   Hours_Today  : Hours_Worked;
   Overtime     : Hours_Worked;
begin
   Day_Loop :
   for Day in Days_Of_Week_T loop
      Put_Line (Day'Image);
      Input_Loop :
      loop
         Hours_Today := Hours_Worked'Value (Get_Line);
         exit Day_Loop when Hours_Today < 0.0;
         if Hours_Today > 24.0 then
            Put_Line ("I don't believe you");
         else
            exit Input_Loop;
         end if;
      end loop Input_Loop;
      if Hours_Today > 8.0 then
         Overtime := Hours_Today - 8.0;
         Hours_Today := Hours_Today + 0.5 * Overtime;
      end if;
      case Day is
         when Monday .. Friday => Total_Worked := Total_Worked + Hours_Today;
         when Saturday         => Total_Worked := Total_Worked + Hours_Today * 1.5;
         when Sunday           => Total_Worked := Total_Worked + Hours_Today * 2.0;
      end case;
   end loop Day_Loop;

   Put_Line (Total_Worked'Image);
end Main;
```

Summary

Summary

- Assignments must satisfy any constraints of LHS
  - Invalid assignments don't alter target
- Intent to do nothing must be explicitly specified
- Case statements alternatives don't fall through
- Any kind of loop can be expressed with building blocks

Array Types

Introduction

Introduction

- Traditional array concept supported to any dimension

```
declare
   type Hours is digits 6;
   type Days is (Mon, Tue, Wed, Thu, Fri, Sat, Sun);
   type Schedule is array (Days) of Hours;
   Workdays : Schedule;
begin
   ...
   Workdays (Mon) := 8.5;
```

Terminology

- *Index type*
  - Specifies the values to be used to access the array components
- *Component type*
  - Specifies the type of values contained by objects of the array type
  - All components are of this same type

```
type Array_T is array (Index_T) of Component_T;
```

Array Type Index Constraints

- Must be of an integer or enumeration type
- May be dynamic
- Default to predefined **Integer**
  - Same rules as for-loop parameter default type
- Allowed to be null range
  - Defines an empty array
  - Meaningful when bounds are computed at run-time
- Can be applied on `type` or `subtype`

```
type Schedule is array (Days range Mon .. Fri) of Float;
type Flags_T is array ( -10 .. 10 ) of Boolean;
-- this may or may not be null range
type Dynamic is array (1 .. N) of Integer;

subtype Line is String (1 .. 80);
subtype Translation is Matrix (1..3, 1..3);
```

Run-Time Index Checking

- Array indices are checked at run-time as needed
- Invalid index values result in `Constraint_Error`

```
procedure Test is
   type List is array (1..10) of Integer;
   A : List;
   K : Integer;
begin
   A := (others => 0);
   K := FOO;
   A (K) := 42; -- runtime error if Foo returns < 1 or > 10
   Put_Line (A(K)'Image);
end Test;
```

Kinds of Array Types

- *Constrained* Array Types
  - Bounds specified by type declaration
  - All objects of the type have the same bounds
- *Unconstrained* Array Types
  - Bounds not specified by type declaration
  - More flexible
  - Allows having objects of the same type but different bounds

```
S1 : String (1 .. 50);
S2 : String (35 .. 95);
S3 : String (1 .. 1024);
```

Constrained Array Types

Examples

```
package Constrained_Array_Types is

   type Array_Of_Integers_T is array (1 .. 10) of Integer;
   type Array_Of_Bits_T is
         array (Natural range 0 .. 31) of Boolean;

   type Color_T is (Red, Green, Blue);
   type Color_Range_T is mod 256;
   type Rgb_T is array (Color_T) of Color_Range_T;

   Ten_Integers : Array_Of_Integers_T;
   One_Word     : Array_Of_Bits_T;
   Color        : Rgb_T;

end Constrained_Array_Types;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/050_array_types.html#constrained-array-types

Constrained Array Type Declarations

- Syntax

```
constrained_array_definition ::=
   array index_constraint of subtype_indication
index_constraint ::= ( discrete_subtype_definition
   {, discrete_subtype_indication} )
discrete_subtype_definition ::=
   discrete_subtype_indication | range
subtype_indication ::= subtype_mark [constraint]
range ::= range_attribute_reference |
   simple_expression .. simple_expression
```

- Examples

```
type Full_Week_T is array (Days) of Float;
type Work_Week_T is array (Days range Mon .. Fri) of Float;
type Weekdays is array (Mon .. Fri) of Float;
type Workdays is array (Weekdays'Range) of Float;
```

Multiple-Dimensioned Array Types

- Declared with more than one index definition
  - Constrained array types
  - Unconstrained array types
- Components accessed by giving value for each index

```
type Three_Dimensioned is
  array (
    Boolean,
    12 .. 50,
    Character range 'a' .. 'z')
    of Integer;
  TD : Three_Dimensioned;
  ...
begin
  TD (True, 42, 'b') := 42;
  TD (Flag, Count, Char) := 42;
```

Tic-Tac-Toe Winners Example

```
-- 9 positions on a board
type Move_Number is range 1 .. 9;
-- 8 ways to win
type Winning_Combinations is
   range 1 .. 8;
-- need 3 positions to win
type Required_Positions is
   range 1 .. 3;
Winning : constant array (
   Winning_Combinations,
   Required_Positions)
   of Move_Number := (1 => (1,2,3),
                      2 => (1,4,7),
                      ...
```

Quiz

```
type Array1_T is array ( 1 .. 8 ) of boolean;
type Array2_T is array ( 0 .. 7 ) of boolean;
X1, Y1 : Array1_T;
X2, Y2 : Array2_T;
```

Which statement is not legal?

A. `X1(1) := Y1(1);`
B. `X1 := Y1;`
C. `X1(1) := X2(1);`
D. `X2 := X1;`

Quiz

```
type Array1_T is array ( 1 .. 8 ) of boolean;
type Array2_T is array ( 0 .. 7 ) of boolean;
X1, Y1 : Array1_T;
X2, Y2 : Array2_T;
```

Which statement is not legal?

A. `X1(1) := Y1(1);`
B. `X1 := Y1;`
C. `X1(1) := X2(1);`
D. `X2 := X1;`

Explanations

A. Legal - elements are `Boolean`
B. Legal - object types match
C. Legal - elements are `Boolean`
D. Although the sizes are the same and the elements are the same, the type is different

Unconstrained Array Types

Examples

```
package Unconstrained_Array_Types is

   type Index_T is range 1 .. 100;
   type List_T is array (Index_T range <>) of Character;
   Wrong : List_T (0 .. 10); -- runtime error
   Right : List_T (11 .. 20);

   type Array_Of_Bits_T is array (Natural range <>) of Boolean;
   Bits8  : Array_Of_Bits_T (0 .. 7);
   Bits16 : Array_Of_Bits_T (1 .. 16);

   type Days_T is (Sun, Mon, Tues, Wed, Thu, Fri, Sat);
   type Schedule_T is array (Days_T range <>) of Float;
   Schedule : Schedule_T (Mon .. Fri);

   Name : String (1 .. 10);

   type Roman_Digit is ('I', 'V', 'X', 'L', 'C', 'D', 'M');
   type Roman_Number is array (Natural range <>) of Roman_Digit;
   Orwellian : constant Roman_Number := "MCMLXXXIV";

end Unconstrained_Array_Types;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/050_array_types.html#unconstrained-array-types

Unconstrained Array Type Declarations

- Do not specify bounds for objects
- Thus different objects of the same type may have different bounds
- Bounds cannot change once set
- Syntax (with simplifications)

```
unconstrained_array_definition ::=
   array ( index_subtype_definition
      {, index_subtype_definition} )
      of subtype_indication
index_subtype_definition ::= subtype_mark range <>
```

- Examples

```
type Index is range 1 .. Integer'Last;
type CharList is array (Index range <>) of Character;
```

Supplying Index Constraints for Objects

- Bounds set by:
  - Object declaration
  - Constant's value
  - Variable's initial value
  - Further type definitions (shown later)
  - Actual parameter to subprogram (shown later)
- Once set, bounds never change

```
type Schedule is array (Days range <>) of Float;
Work : Schedule (Mon .. Fri);
All_Days : Schedule (Days);
```

Bounds Must Satisfy Type Constraints

- Must be somewhere in the range of possible values specified by the type declaration
- `Constraint_Error` otherwise

```
type Index is range 1 .. 100;
type List is array (Index range <>) of Character;
...
Wrong : List (0 .. 10);  -- runtime error
OK : List (50 .. 75);
```

"String" Types

- Language-defined unconstrained array types
  - Allow double-quoted literals as well as aggregates
  - Always have a character component type
  - Always one-dimensional
- Language defines various types
  - **String**, with **Character** as component

    ```
    subtype Positive is Integer range 1 .. Integer'Last;
    type String is array (Positive range <>) of Character;
    ```

  - **Wide_String**, with **Wide_Character** as component
  - **Wide_Wide_String**, with **Wide_Wide_Character** as component
- Can be defined by applications too

Application-Defined String Types

- Like language-defined string types
  - Always have a character component type
  - Always one-dimensional
- Recall character types are enumeration types with at least one character literal value

```
type Roman_Digit is ('I', 'V', 'X', 'L', 'C', 'D', 'M');
type Roman_Number is array (Positive range <>)
    of Roman_Digit;
Orwellian : constant Roman_Number := "MCMLXXXIV";
```

Specifying Constraints via Initial Value

- Lower bound is `Index_subtype'First`
- Upper bound is taken from number of items in value

```
subtype Positive is Integer range 1 .. Integer'Last;
type String is array (Positive range <>)
    of Character;
...
M : String := "Hello World!";
-- M'first is positive'first (1)

type Another_String is array (Integer range <>)
    of Character;
...
M : Another_String := "Hello World!";
-- M'first is integer'first
```

No Unconstrained Component Types

- Arrays: consecutive elements of the exact **same type**
- Component size must be **defined**
  - No unconstrained types
  - Constrained subtypes allowed

```
type Good is array (1 .. 10) of String (1 .. 20); -- OK
type Bad is array (1 .. 10) of String; -- Illegal
```

Arrays of Arrays

- Allowed (of course!)
  - As long as the "component" array type is constrained
- Indexed using multiple parenthesized values
  - One per array

```
declare
   type Array_of_10 is array (1..10) of Integer;
   type Array_of_Array is array (Boolean) of Array_of_10;
   A : Array_of_Array;
begin
   ...
   A (True)(3) := 42;
```

Quiz

```
type Array_T is array (Integer range <>) of Integer;
subtype Array1_T is Array_T (1 .. 4);
subtype Array2_T is Array_T (0 .. 3);
X : Array_T  := (1, 2, 3, 4);
Y : Array1_T := (1, 2, 3, 4);
Z : Array2_T := (1, 2, 3, 4);
```

Which statement is illegal?

A. `X (1) := Y (1);`
B. `Y (1) := Z (1);`
C. `Y := X;`
D. `Z := X;`

Quiz

```
type Array_T is array (Integer range <>) of Integer;
subtype Array1_T is Array_T (1 .. 4);
subtype Array2_T is Array_T (0 .. 3);
X : Array_T  := (1, 2, 3, 4);
Y : Array1_T := (1, 2, 3, 4);
Z : Array2_T := (1, 2, 3, 4);
```

Which statement is illegal?

A. `X (1) := Y (1);`
B. `Y (1) := Z (1);`
C. `Y := X;`
D. `Z := X;`

Explanations

A. `Array_T` starts at `Integer'First` not `1`
B. OK, both in range
C. OK, same type and size
D. OK, same type and size

Attributes

Examples

```
procedure Attributes is

   type Array_Of_Bits_T is array (Natural range <>) of Boolean;
   Bits8 : Array_Of_Bits_T (0 .. 7);

   type Array_Of_Bitstrings_T is
     array (Natural range <>, Natural range <>) of Boolean;
   Bitstrings : Array_Of_Bitstrings_T (1 .. 10, 0 .. 16);

   Value : Natural;

begin

   Value := 0;
   for Index in Bits8'First .. Bits8'Last loop
      if Bits8 (Index) then
         Value := Value + 2**(Index - Bits8'First);
      end if;
   end loop;

   for String_Index in Bitstrings'Range (1) loop
      Value := 0;
      for Bit_Index in Bitstrings'Range (2) loop
         if Bitstrings (String_Index, Bit_Index) then
            Value := Value + 2**(Bit_Index - Bitstrings'First (2));
         end if;
      end loop;
   end loop;

end Attributes;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/050_array_types.html#attributes

Array Attributes

- Return info about array index bounds

  O'Length number of array components

  O'First value of lower index bound

  O'Last value of upper index bound

  O'Range another way of saying `T'First .. T'Last`

- Meaningfully applied to constrained array types
  - Only constrained array types provide index bounds
  - Returns index info specified by the type (hence all such objects)
- Meaningfully applied to array objects
  - Returns index info for the object
  - Especially useful for objects of unconstrained array types

Attributes' Benefits

- Allow code to be more robust
  - Relationships are explicit
  - Changes are localized
- Optimizer can identify redundant checks

```
declare
   type List is array (5 .. 15) of Integer;
   L : List;
   List_Index : Integer range List'Range := List'First;
   Count : Integer range  0 .. List'Length := 0;
begin
   ...
   for K in L'Range loop
      L (K) := K * 2;
   end loop;
```

Nth Dimension Array Attributes

- Attribute with **parameter**

```
T'Length (n)
T'First (n)
T'Last (n)
T'Range (n)
```

- n is the dimension
  - defaults to 1

```
type Two_Dimensioned is array
   (1 .. 10, 12 .. 50) of T;
TD : Two_Dimensioned;
```

- TD'First (2) = 12
- TD'Last (2) = 50
- TD'Length (2) = 39
- TD'First = TD'First (1) = 1

Quiz

```
subtype Index1_T is Integer range 0 .. 7;
subtype Index2_T is Integer range 1 .. 8;
type Array_T is array (Index1_T, Index2_T) of Integer;
X : Array_T;
```

Which comparison is False?

A. `X'Last(2) = Index2_T'Last`
B. `X'Last(1)*X'Last(2) = X'Length(1)*X'Length(2)`
C. `X'Length(1) = X'Length(2)`
D. `X'Last(1) = 7`

Quiz

```
subtype Index1_T is Integer range 0 .. 7;
subtype Index2_T is Integer range 1 .. 8;
type Array_T is array (Index1_T, Index2_T) of Integer;
X : Array_T;
```

Which comparison is False?

A. `X'Last(2) = Index2_T'Last`
B. *`X'Last(1)*X'Last(2) = X'Length(1)*X'Length(2)`*
C. `X'Length(1) = X'Length(2)`
D. `X'Last(1) = 7`

Explanations

A. $8 = 8$
B. $7*8 /= 8*8$
C. $8 = 8$
D. $7 = 7$

Operations

Examples

```
with Ada.Text_IO; use Ada.Text_IO;
procedure Operations is

   type Boolean_Array_T is array (0 .. 15) of Boolean;
   Bool1, Bool2, Bool3 : Boolean_Array_T;

   type Integer_Array_T is array (1 .. 100) of Integer;
   Int1, Int2 : Integer_Array_T;

   Str1 : String (1 .. 10) := (others => 'X');
   Str2 : String (2 .. 9)  := (others => '-');

   Flag : Boolean;

begin

   Bool3 := Bool1 or Bool2;
   Flag  := Int1 > Int2;
   Put_Line (Flag'Image);

   declare
      Str3 : String := Str1 & Str2;
   begin
      Str3
        (Str3'First .. Str3'First + 1) := "**";
      Str3 (1 .. 4)                    := Str1 (1 .. 2) & Str2 (8 .. 9);
      Put_Line (Str3);
   end;

   if Int1 (1) in Bool3'Range then
      Bool3 (Int1 (1)) := Int1 (1) > Int2 (1);
      Put_Line (Boolean'Image (Bool3 (Int1 (1))));
   end if;

end Operations;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/050_array_types.html#operations

Object-Level Operations

- Assignment of array objects

```
A := B;
```

- Equality and inequality

```
if A = B then
```

- Conversions

```
C := Foo ( B );
```

  - Component types must be the same type
  - Index types must be the same or convertible
  - Dimensionality must be the same
  - Bounds must be compatible (not necessarily equal)

Extra Object-Level Operations

- *Only for 1-dimensional arrays!*
- Concatenation

```
type String_Type is array
  (Integer range <>) of Character;
A : constant String_Type := "foo";
B : constant String_Type := "bar";
C : constant String_Type := A & B;
-- C now contains "foobar"
```

- Relational (for discrete component types)
- Logical (for Boolean component type)
- Slicing
  - Portion of array

Examples

```
with Ada.Text_IO; use Ada.Text_IO;
procedure Slices is
   procedure Explicit_Indices is
      Full_Name : String (1 .. 20) := "Barney    Rubble    ";
   begin
      Put_Line (Full_Name);
      Full_Name (1 .. 10) := "Betty     ";
      Put_Line (Full_Name (1 .. 10)); -- first half of name
      Put_Line (Full_Name (11 .. 20)); -- second half of name
   end Explicit_Indices;

   procedure Subtype_Indices is
      subtype First_Name is Positive range 1 .. 10;
      subtype Last_Name is Positive range 11 .. 20;
      Full_Name : String (First_Name'First .. Last_Name'Last) :=
        "Fred      Flintstone";
   begin
      Put_Line (Full_Name);
      Full_Name (First_Name) := "Wilma     ";
      Put_Line (Full_Name (First_Name)); -- first half of name
      Put_Line (Full_Name (Last_Name)); -- second half of name
   end Subtype_Indices;
begin
   Explicit_Indices;
   Subtype_Indices;
end Slices;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/080_expressions.html#slices

Slicing

- Contiguous subsection of an array
- On any **one-dimensional** array type
  - Any component type

```
procedure Test is
   S1 : String (1 .. 9) := "Hi Adam!!";
   S2 : String := "We love    !";
begin
   S2 (9..11) := S1 (4..6);
   Put_Line (S2);
end Test;
```

Result: `We love Ada!`

Slicing With Explicit Indexes

- Imagine a requirement to have a name with two parts: first and last

```
declare
   Full_Name : String (1 .. 20);
begin
   Put_Line (Full_Name);
   Put_Line (Full_Name (1..10));  -- first half of name
   Put_Line (Full_Name (11..20)); -- second half of name
```

Slicing With Named Subtypes for Indexes

- Subtype name indicates the slice index range
  - Names for constraints, in this case index constraints
- Enhances readability and robustness

```
procedure Test is
   subtype First_Name is Positive range 1 .. 10;
   subtype Last_Name is Positive range 11 .. 20;
   Full_Name : String(First_Name'First..Last_Name'Last);
begin
   Put_Line(Full_Name(First_Name)); -- Full_Name(1..10)
   if Full_Name (Last_Name) = SomeString then ...
```

Dynamic Subtype Constraint Example

- Useful when constraints not known at compile-time
- Example: remove file name extension

```
File_Name
   (File_Name'First
   ..
   Index (File_Name, '.', Direction => Backward));
```

Quiz

```
type Index_T is range 1 .. 10;
type OneD_T is array (Index_T) of Boolean;
type ThreeD_T is array (Index_T, Index_T, Index_T) of OneD_T;
A : ThreeD_T;
B : OneD_T;
```

Which statement is illegal?

A. `B(1) := A(1,2,3)(1) or A(4,3,2)(1);`
B. `B := A(2,3,4) and A(4,3,2);`
C. `A(1,2,3..4) := A(2,3,4..5);`
D. `B(3..4) := B(4..5)`

Quiz

```
type Index_T is range 1 .. 10;
type OneD_T is array (Index_T) of Boolean;
type ThreeD_T is array (Index_T, Index_T, Index_T) of OneD_T;
A : ThreeD_T;
B : OneD_T;
```

Which statement is illegal?

A. `B(1) := A(1,2,3)(1) or A(4,3,2)(1);`
B. `B := A(2,3,4) and A(4,3,2);`
C. *`A(1,2,3..4) := A(2,3,4..5);`*
D. `B(3..4) := B(4..5)`

Explanations

A. All three objects are just boolean values
B. An element of `A` is the same type as `B`
C. No slicing of multi-dimensional arrays
D. Slicing allowed on single-dimension arrays

Operations Added for Ada2012

Examples

```
with Ada.Text_IO; use Ada.Text_IO;
procedure Operations_Added_For_Ada2012 is

   type Integer_Array_T is array (1 .. 10) of Integer with
      Default_Component_Value => -1;
   Int_Array : Integer_Array_T;

   type Matrix_T is array (1 .. 3, 1 .. 3) of Integer with
      Default_Component_Value => -1;
   Matrix : Matrix_T;

begin

   for Index in Int_Array'First + 1 .. Int_Array'Last - 1 loop
      Int_Array (Index) := Index * 10;
   end loop;
   for Item of Int_Array loop
      Put_Line (Integer'Image (Item));
   end loop;

   for Index1 in Matrix_T'First (1) + 1 .. Matrix'Last (1) loop
      for Index2 in Matrix_T'First (2) + 1 .. Matrix'Last (2) loop
         Matrix (Index1, Index2) := Index1 * 100 + Index2;
      end loop;
   end loop;
   for Item of reverse Matrix loop
      Put_Line (Integer'Image (Item));
   end loop;

end Operations_Added_For_Ada2012;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/050_array_types.html#operations-added-for-ada2012

Default Initialization for Array Types

Ada 2012

- Supports constrained and unconstrained array types
- Supports arrays of any dimensionality
  - No matter how many dimensions, there is only one component type
- Uses aspect **Default_Component_Value**

```
type Vector is array (Positive range <>) of Float
   with Default_Component_Value => 0.0;
```

Two High-Level For-Loop Kinds

Ada 2012

- For arrays and containers
  - Arrays of any type and form
  - Iterable containers
    - Those that define iteration (most do)
    - Not all containers are iterable (e.g., priority queues)!
- For iterator objects
  - Known as "generalized iterators"
  - Language-defined, e.g., most container data structures
- User-defined iterators too
- We focus on the arrays/containers form for now

Array/Container For-Loops

Ada 2012

- Work in terms of elements within an object
- Syntax hides indexing/iterator controls

```
for name of [reverse] array_or_container_object loop
...
end loop;
```

- Starts with "first" element unless you reverse it
- Loop parameter name is a constant if iterating over a constant, a variable otherwise

Array Component For-Loop Example

Ada 2012

- Given an array

```
Primes : constant array (1 .. 5) of Integer :=
   (2, 3, 5, 7, 11);
```

- Component-based looping would look like

```
for P of Primes loop
   Put_Line (Integer'Image (P));
end loop;
```

- While index-based looping would look like

```
for P in Primes'range loop
   Put_Line (Integer'Image (Primes(P)));
end loop;
```

For-Loops with Multidimensional Arrays

Ada 2012

- Same syntax, regardless of number of dimensions
- As if a set of nested loops, one per dimension
  - Last dimension is in innermost loop, so changes fastest
- In low-level format looks like

```
for each row loop
   for each column loop
      print Identity (
         row, column)
   end loop
end loop
```

```
declare
   subtype Rows is Positive;
   subtype Columns is Positive;
   type Matrix is array
      (Rows range <>,
       Columns range <>) of Float;
     Identity : constant Matrix
        (1..3, 1..3) :=
          ((1.0, 0.0, 0.0),
           (0.0, 1.0, 0.0),
           (0.0, 0.0, 1.0));
begin
   for C of Identity loop
     Put_Line (Float'Image(C));
   end loop;
```

Quiz

```
declare
   type Array_T is array (1..3, 1..3) of Integer
      with Default_Component_Value => 1;
   A : Array_T;
begin
   for I in Index_T range 2 .. 3 loop
      for J in Index_T range 2 .. 3 loop
         A (I, J) := I * 10 + J;
      end loop;
   end loop;
   for I of reverse A loop
      Put (I'Image);
   end loop;
end;
```

Which output is correct?

A. 1 1 1 1 22 23 1 32 33
B. 33 32 1 23 22 1 1 1 1
C. 0 0 0 0 22 23 0 32 33
D. 33 32 0 23 22 0 0 0 0

NB: Without `Default_Component_Value`, init. values are random

Quiz

```
declare
   type Array_T is array (1..3, 1..3) of Integer
      with Default_Component_Value => 1;
   A : Array_T;
begin
   for I in Index_T range 2 .. 3 loop
      for J in Index_T range 2 .. 3 loop
         A (I, J) := I * 10 + J;
      end loop;
   end loop;
   for I of reverse A loop
      Put (I'Image);
   end loop;
end;
```

Which output is correct?

A. 1 1 1 1 22 23 1 32 33
B. ***33 32 1 23 22 1 1 1 1***
C. 0 0 0 0 22 23 0 32 33
D. 33 32 0 23 22 0 0 0 0

Explanations

A. There is a `reverse`
B. Yes
C. Default value is 1
D. No

NB: Without `Default_Component_Value`, init. values are random

Aggregates

Examples

```
procedure Aggregates is

   type Days_T is (Mon, Tue, Wed, Thu, Fri, Sat, Sun);
   type Working_T is array (Days_T) of Float;
   Week : Working_T := (others => 0.0);

   Start, Finish : Days_T;

   type Array_T is array (Days_T range <>) of Boolean;
   List : Array_T (Mon .. Start) := (others => False);

begin

   Week := (8.0, 8.0, 8.0, 8.0, 8.0, 0.0, 0.0);
   Week := (Sat => 0.0, Sun => 0.0, Mon .. Fri => 8.0);
   Week := (Sat | Sun => 0.0, Mon .. Fri => 8.0);
   -- Compile error
   -- Week := (8.0, 8.0, 8.0, 8.0, 8.0, Sat => 0.0, Sun => 0.0);

   if Week = (10.0, 10.0, 10.0, 10.0, 0.0, 0.0, 0.0) then
      null; -- four-day week
   end if;

   Week := (8.0, others => 0.0);
   Week := (8.0, others => <>); -- Ada2012: use previously set values

   -- Compile error
   -- Week := (Week'First .. Start => 0.0, Start .. Finish => 8.0,
   --          Finish .. Week'Last => 0.0);

end Aggregates;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/050_array_types.html#aggregates

Aggregates

- Literals for composite types
  - Array types
  - Record types
- Two distinct forms
  - Positional
  - Named
- Syntax (simplified):

```
component_expr ::=
  expression -- Defined value
  | <>       -- Default value

array_aggregate ::= (
    {component_expr ,}                              -- Positional
  | {discrete_choice_list => component_expr,}) -- Named
  -- Default "others" indices
  [others => expression]
```

Aggregate "Positional" Form

- Specifies array component values explicitly
- Uses implicit ascending index values

```
type Days is (Mon, Tue, Wed, Thu, Fri, Sat, Sun);
type Working is array (Days) of Boolean;
Week : Working;
...
-- Saturday and Sunday are False, everything else true
Week := (True, True, True, True, True, False, False);
```

Aggregate "Named" Form

- Explicitly specifies both index and corresponding component values
- Allows any order to be specified
- Ranges and choice lists are allowed (like case choices)

```
type Days is (Mon, Tue, Wed, Thu, Fri, Sat, Sun);
type Working is array (Days) of Boolean;
Week : Working;
...
Week := (Sat => False, Sun => False, Mon..Fri => True);
Week := (Sat | Sun => False, Mon..Fri => True);
```

Combined Aggregate Forms Not Allowed

- Some cases lead to ambiguity, therefore never allowed for array types
- Are only allowed for record types (shown in subsequent section)

```
type Days is (Mon, Tue, Wed, Thu, Fri, Sat, Sun);
type Working is array (Days) of Boolean;
Week : Working;
...
Week := (True, True, True, True, True, False, False);
Week := (Sat => False, Sun => False, Mon..Fri => True);
Week := (True, True, True, True, True,
         Sat => False, Sun => False); -- invalid
Week := (Sat | Sun => False, Mon..Fri => True);
```

Aggregates Are True Literal Values

- Used any place a value of the type may be used

```
type Schedule is array (Mon .. Fri) of Float;
Work : Schedule;
Normal : constant Schedule := (8.0, 8.0, 8.0, 8.0, 8.0);
...
Work := (8.5, 8.5, 8.5, 8.5, 6.0);
...
if Work = Normal then ...
...
if Work = (10.0, 10.0, 10.0, 10.0, 0.0) then -- 4-day week .
```

Aggregate Consistency Rules

- Must always be complete
  - They are literals, after all
  - Each component must be given a value
  - But defaults are possible (more in a moment)
- Must provide only one value per index position
  - Duplicates are detected at compile-time
- Compiler rejects incomplete or inconsistent aggregates

```
Week := (Sat => False,
         Sun => False,
         Mon .. Fri => True,
         Wed => False);
```

"Others"

- Indicates all components not yet assigned a value
- All remaining components get this single value
- Similar to case statement's **others**
- Can be used to apply defaults too

```
type Schedule is array (Days) of Float;
Work : Schedule;
Normal : constant Schedule := (8.0, 8.0, 8.0, 8.0, 8.0,
                               others => 0.0);
```

Nested Aggregates

- For multiple dimensions
- For arrays of composite component types

```
type Matrix is array (Positive range <>,
                      Positive range <>) of Float;
Mat_4x2 : Matrix (1..4, 1..2) := (1 =>  (2.5, 3.0),
                                  2 =>  (1.5, 0.0),
                                  3 =>  (2.1, 0.0),
                                  4 =>  (9.0, 0.0) );
```

Tic-Tac-Toe Winners Example

```
type Move_Number is range 1 .. 9;
-- 8 ways to win
type Winning_Combinations is range 1 .. 8;
-- need 3 places to win
type Required_Positions   is range 1 .. 3;
Winning : constant array (Winning_Combinations,
                          Required_Positions) of
   Move_Number := ( -- rows
                    1 => (1, 2, 3),
                    2 => (4, 5, 6),
                    3 => (7, 8, 9),
                    -- columns
                    4 => (1, 4, 7),
                    5 => (2, 5, 8),
                    6 => (3, 6, 9),
                    -- diagonals
                    7 => (1, 5, 9),
                    8 => (3, 5, 7)  );
```

Defaults Within Array Aggregates

Ada 2005

- Specified via the `box` notation
- Value for component is thus taken as for stand-alone object declaration
  - So there may or may not be a defined default!
- Can only be used with "named association" form
  - But `others` counts as named form
- Syntax

```
discrete_choice_list => <>
```

- Example

```
type List is array (1 .. N) of Integer;
Primes : List := (1 => 2, 2 .. N => <>);
```

Named Format Aggregate Rules

- Bounds cannot overlap
  - Index values must be specified once and only once
- All bounds must be static
  - Avoids run-time cost to verify coverage of all index values
  - Except for single choice format

```
type List is array (Integer range <>) of Float;
Ages : List (1 .. 10) := (1 .. 3 => X, 4 .. 10 => Y);
-- illegal: 3 appears twice
Overlap : List (1 .. 10) := (1 .. 4 => X, 3 .. 10 => Y);
N, M, K, L : Integer;
-- illegal: cannot determine if
-- every index covered at compile time
Not_Static : List (1 .. 10) := (M .. N => X, K .. L => Y);
-- This is legal
Values : List (1 .. N) := (1 .. N => X);
```

Quiz

```
type Array_T is array (1 .. 5) of Integer;
X : Array_T;
J : Integer := X'First;
```

Which statement is correct?

A. `X := (1, 2, 3, 4 => 4, 5 => 5);`
B. `X := (1..3 => 100, 4..5 => -100, others => -1);`
C. `X := (J => -1, J + 1..X'Last => 1);`
D. `X := (1..3 => 100, 3..5 => 200);`

Quiz

```
type Array_T is array (1 .. 5) of Integer;
X : Array_T;
J : Integer := X'First;
```

Which statement is correct?

A. `X := (1, 2, 3, 4 => 4, 5 => 5);`
B. *`X := (1..3 => 100, 4..5 => -100, others => -1);`*
C. `X := (J => -1, J + 1..X'Last => 1);`
D. `X := (1..3 => 100, 3..5 => 200);`

Explanations

A. Cannot mix positional and named notation
B. Correct - others not needed but is allowed
C. Dynamic values must be the only choice. (This could be fixed by making J a constant.)
D. Overlapping index values (3 appears more than once)

Anonymous Array Types

Anonymous Array Types

- Array objects need not be of a named type
  `A : array ( 1 .. 3 ) of B;`
- Without a type name, no object-level operations
  - Cannot be checked for type compatibility
  - Operations on components are still ok if compatible

```
declare
-- These are not same type!
   A, B : array (Foo) of Bar;
begin
   A := B;   -- illegal
   B := A;   -- illegal
   -- legal assignment of value
   A(J) := B(K);
end;
```

Lab

Array Lab

- Requirements
  - Create an array type whose index is days of the week and each element is a number
  - Create two objects of the array type, one of which is constant
  - Perform the following operations
    - Copy the constant object to the non-constant object and
    - Print the contents of the non-constant object
    - Use an array aggregate to initialize the non-constant object
    - For each element of the array, print the array index and the value
    - Move part ("source") of the non-constant object to another part ("destination"), and then clear the source location
    - Print the contents of the non-constant object
- Hints
  - When you want to combine multiple strings (which are arrays!) use the concatenation operator (**&**)
  - Slices are how you access part of an array
  - Use aggregates (either named or positional) to initialize data

Multiple Dimensions

- Requirements
  - For each day of the week, you need an array of three strings containing names of workers for that day
  - Two sets of workers: weekend and weekday, but the store is closed on Wednesday (no workers)
  - Initialize the array and then print it hierarchically

Array Lab Solution - Declarations

```
with Ada.Text_IO; use Ada.Text_IO;
procedure Main is

   type Days_Of_Week_T is
      (Mon, Tue, Wed, Thu, Fri, Sat, Sun);
   type Unconstrained_Array_T is
      array (Days_Of_Week_T range <>) of Natural;

   Const_Arr : constant Unconstrained_Array_T := (1, 2, 3, 4
   Array_Var : Unconstrained_Array_T (Days_Of_Week_T);

   type Name_T is array (1 .. 6) of Character;
   Weekly_Staff : array (Days_Of_Week_T, 1 .. 3) of Name_T;
```

Array Lab Solution - Implementation

```
begin
   Array_Var := Const_Arr;
   for Item of Array_Var loop
      Put_Line (Item'Image);
   end loop;
   New_Line;

   Array_Var :=
     (Mon => 111, Tue => 222, Wed => 333, Thu => 444, Fri => 555, Sat => 666,
      Sun => 777);
   for Index in Array_Var'Range loop
      Put_Line (Index'Image & " => " & Array_Var (Index)'Image);
   end loop;
   New_Line;

   Array_Var (Mon .. Wed) := Const_Arr (Wed .. Fri);
   Array_Var (Wed .. Fri) := (others => Natural'First);
   for Item of Array_Var loop
      Put_Line (Item'Image);
   end loop;
   New_Line;

   Weekly_Staff := (Mon | Tue | Thu | Fri => ("Fred  ", "Barney", "Wilma "),
                    Wed    => ("closed", "closed", "closed"),
                    others => ("Pinky ", "Inky  ", "Blinky"));

   for Day in Weekly_Staff'Range (1) loop
      Put_Line (Day'Image);
      for Staff in Weekly_Staff'Range (2) loop
         Put_Line ("  " & String (Weekly_Staff (Day, Staff)));
      end loop;
   end loop;
end Main;
```

Summary

Final Notes on Type **String**

- Any single-dimensioned array of some character type is a *string type*
  - Language defines types **String**, **Wide_String**, etc.
- Just another array type: no null termination
- Language-defined support defined in Appendix A
  - **Ada.Strings.***
  - Fixed-length, bounded-length, and unbounded-length
  - Searches for pattern strings and for characters in program-specified sets
  - Transformation (replacing, inserting, overwriting, and deleting of substrings)
  - Translation (via a character-to-character mapping)

Summary

- Any dimensionality directly supported
- Component types can be any (constrained) type
- Index types can be any discrete type
  - Integer types
  - Enumeration types
- Constrained array types specify bounds for all objects
- Unconstrained array types leave bounds to the objects
  - Thus differently-sized objects of the same type
- Default initialization for large arrays may be expensive!
- Anonymously-typed array objects used in examples for brevity but that doesn't mean you should in real programs

Record Types

Introduction

Syntax and Examples

- Syntax (simplified)

```
type T is record
   Component_Name : Type [:= Default_Value];
   ...
end record;

type T_Empty is null record;
```

- Example

```
type Record1_T is record
   Field1 : integer;
   Field2 : boolean;
end record;
```

- Records can be **discriminated** as well

```
type T ( Size : Natural := 0 ) is record
   Text : String (1 .. Size);
end record;
```

Components Rules

Examples

```
with Ada.Text_IO; use Ada.Text_IO;
procedure Components_Rules is
   type File_T is record
      Name    : String (1 .. 12);
      Mode    : File_Mode;
      Size    : Integer range 0 .. 1_024;
      Is_Open : Boolean;
      -- Anonymous_Component : array (1 .. 3) of Integer;
      -- Constant_Component  : constant Integer := 123;
      -- Self_Reference      : File_T;
   end record;
   File : File_T;
begin
   File.Name    := "Filename.txt";
   File.Mode    := In_File;
   File.Size    := 0;
   File.Is_Open := False;
   Put_Line (File.Name);
end Components_Rules;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/060_record_types.html#components-rules

Characteristics of Components

- **Heterogeneous** types allowed
- Referenced **by name**
- May be no components, for **empty records**
- **No** anonymous types (e.g., arrays) allowed
- **No** constant components
- **No** recursive definitions

Components Declarations

- Multiple declarations are allowed (like objects)

```
type Several is record
   A, B, C : Integer;
end record;
```

- Recursive definitions are not allowed

```
type Not_Legal is record
  A, B : Some_Type;
  C : Not_Legal;
end record;
```

"Dot" Notation for Components Reference

```
type Months_T is (January, February, ..., December);
type Date is record
   Day : Integer range 1 .. 31;
   Month : Months_T;
   Year : Integer range 0 .. 2099;
end record;
Arrival : Date;
...
Arrival.Day := 27;  -- components referenced by name
Arrival.Month := November;
Arrival.Year := 1990;
```

- Can reference nested components

```
Employee
   .Birth_Date
     .Month := March;
```

Quiz

```
type Record_T is record
   -- Definition here
end record;
```

Which record definition is legal?

A. `Component_1 : array (1 .. 3) of Boolean`
B. `Component_2, Component_3 :  Integer`
C. `Component_1 : Record_T`
D. `Component_1 : constant Integer := 123`

Quiz

```
type Record_T is record
   -- Definition here
end record;
```

Which record definition is legal?

A. `Component_1 : array (1 .. 3) of Boolean`
B. *`Component_2, Component_3 :  Integer`*
C. `Component_1 : Record_T`
D. `Component_1 : constant Integer := 123`

A. Anonymous types not allowed
B. Correct
C. No recursive definition
D. No constant component

Quiz

```
type Cell is record
   Val : Integer;
   Message : String;
end record;
```

Is the definition legal?

A. Yes
B. No

Quiz

```
type Cell is record
   Val : Integer;
   Message : String;
end record;
```

Is the definition legal?

A. Yes
B. ***No***

A `record` definition cannot have a component of an indefinite type. `String` is indefinite if you don't specify its size.

Operations

Examples

```
with Ada.Text_IO; use Ada.Text_IO;
procedure Operations is
   type Date_T is record
      Day   : Integer range 1 .. 31;
      Month : Positive range 1 .. 12;
      Year  : Natural range 0 .. 2_099;
   end record;
   type Personal_Information_T is record
      Name      : String (1 .. 10);
      Birthdate : Date_T;
   end record;
   type Employee_Information_T is record
      Number               : Positive;
      Personal_Information : Personal_Information_T;
   end record;
   Employee : Employee_Information_T;
begin
   Employee.Number                                := 1_234;
   Employee.Personal_Information.Name             := "Fred Smith";
   Employee.Personal_Information.Birthdate.Year := 2_020;
   Put_Line (Employee.Number'Image);
end Operations;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/060_record_types.html#operations

Available Operations

- Predefined
  - Equality (and thus inequality)

    ```
    if A = B then
    ```

  - Assignment

    ```
    A := B;
    ```

  - Component-level operations
    - Based on components' types

      ```
      if A.component < B.component then
      ```

- User-defined
  - Subprograms

Assignment Examples

```
declare
  type Complex is record
      Real : Float;
      Imaginary : Float;
    end record;
  ...
  Phase1 : Complex;
  Phase2 : Complex;
begin
  ...
    -- object reference
   Phase1 := Phase2;  -- entire object reference
   -- component references
   Phase1.Real := 2.5;
   Phase1.Real := Phase2.Real;
end;
```

Constant and Limited

- Both un-assignable
- Constants can **never** change
  - May be inlined
  - Carried by the **object**
- Limited cannot be **copied** or **compared**
  - May be modified component-wise
  - Carried by the **type**

```
type Lim is limited record
    A, B : Integer;
end record;

L1, L2 : Lim := (1, 2); -- Initial value OK

L1 := L2; -- Illegal
if L1 /= L2 then -- Illegal
[...]
```

Aggregates

Examples

```
with Ada.Text_IO; use Ada.Text_IO;
procedure Aggregates is

   type Date_T is record
      Day   : Integer range 1 .. 31;
      Month : Positive range 1 .. 12;
      Year  : Natural range 0 .. 2_099;
   end record;
   type Personal_Information_T is record
      Name      : String (1 .. 10);
      Birthdate : Date_T;
   end record;
   type Employee_Information_T is record
      Number               : Positive;
      Personal_Information : Personal_Information_T;
   end record;
   Birthdate            : Date_T;
   Personal_Information : Personal_Information_T;
   Employee             : Employee_Information_T;
begin
   Birthdate := (25, 12, 2_001);
   Put_Line
     (Birthdate.Year'Image & Birthdate.Month'Image & Birthdate.Day'Image);
   Personal_Information := (Name => "Jane Smith", Birthdate => (14, 2, 2_002));
   Put_Line
     (Personal_Information.Birthdate.Year'Image &
      Personal_Information.Birthdate.Month'Image &
      Personal_Information.Birthdate.Day'Image);
   Employee := (1_234, Personal_Information => Personal_Information);
   Put_Line
     (Employee.Personal_Information.Birthdate.Year'Image &
      Employee.Personal_Information.Birthdate.Month'Image &
      Employee.Personal_Information.Birthdate.Day'Image);
   Birthdate := (Month => 1, others => 2);
   Put_Line
     (Birthdate.Year'Image & Birthdate.Month'Image & Birthdate.Day'Image);
end Aggregates;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/060_record_types.html#aggregates

Aggregates

- Literal values for composite types
  - As for arrays
  - Default value / selector: `<>`, `others`
- Can use both **named** and **positional**
  - Unambiguous
- Example:

```
(Pos_1_Value,
 Pos_2_Value,
 Component_3 => Pos_3_Value,
 Component_4 => <>, -- Default value (Ada 2005)
 others => Remaining_Value)
```

Record Aggregate Examples

```
type Color_T is (Red);
type Car_T is record
   Color    : Color_T;
   Plate_No : String (1 .. 6);
   Year     : Natural;
end record;
type Complex_T is record
   Real      : Float;
   Imaginary : Float;
end record;

declare
   Car   : Car_T     := (Red, "ABC123", Year => 2_022);
   Phase : Complex_T := (1.2, 3.4);
begin
   Phase := (Real => 5.6, Imaginary => 7.8);
end;
```

Aggregate Completeness

- All component values must be accounted for
  - Including defaults via box
- Allows compiler to check for missed components
- Type definition

```
type Struct is record
      A : Integer;
      B : Integer;
      C : Integer;
      D : Integer;
   end record;
S : Struct;
```

- Compiler will not catch the missing component

```
S.A := 10;
S.B := 20;
S.C := 12;
Send (S);
```

- Aggregate must be complete - compiler error

```
S := (10, 20, 12);
Send (S);
```

Named Associations

- **Any** order of associations
- Provides more information to the reader
  - Can mix with positional
- Restriction
  - Must stick with named associations **once started**

```
type Complex is record
    Real : Float;
    Imaginary : Float;
  end record;
Phase : Complex := (0.0, 0.0);
...
Phase := (10.0, Imaginary => 2.5);
Phase := (Imaginary => 12.5, Real => 0.212);
Phase := (Imaginary => 12.5, 0.212); -- illegal
```

Nested Aggregates

```
type Months_T is ( January, February, ..., December);
type Date is record
   Day   : Integer range 1 .. 31;
   Month : Months_T;
   Year  : Integer range 0 .. 2099;
end record;
type Person is record
   Born : Date;
   Hair : Color;
end record;
John : Person    := ( (21, November, 1990), Brown );
Julius : Person  := ( (2, August, 1995), Blond );
Heather : Person := ( (2, March, 1989), Hair => Blond );
Megan : Person   := (Hair => Blond,
                     Born => (16, December, 2001));
```

Aggregates with Only One Component

- **Must** use named form
- Same reason as array aggregates

```
type Singular is record
   A : Integer;
end record;

S : Singular := (3);           -- illegal
S : Singular := (3 + 1);       -- illegal
S : Singular := (A => 3 + 1); -- required
```

Aggregates with **others**

- Indicates all components not yet specified (like arrays)
- All `others` get the same value
  - They must be the **exact same** type

```
type Poly is record
   A : Real;
   B, C, D : Integer;
end record;

P : Poly := (2.5, 3, others => 0);

type Homogeneous is record
   A, B, C : Integer;
end record;

Q : Homogeneous := (others => 10);
```

Quiz

What is the result of building and running this code?

```
procedure Main is
   type Record_T is record
      A, B, C : Integer := 0;
   end record;

   V : Record_T := (A => 1);
begin
   Put_Line (Integer'Image (V.A));
end Main;
```

A. 0
B. 1
C. Compilation error
D. Runtime error

Quiz

What is the result of building and running this code?

```
procedure Main is
   type Record_T is record
      A, B, C : Integer := 0;
   end record;

   V : Record_T := (A => 1);
begin
   Put_Line (Integer'Image (V.A));
end Main;
```

A. 0
B. 1
C. ***Compilation error***
D. Runtime error

The aggregate is incomplete. The aggregate must specify all components, you could use box notation `(A => 1, others => <>)`

Quiz

What is the result of building and running this code?

```
procedure Main is
   type My_Integer is new Integer;
   type Record_T is record
      A, B, C : Integer := 0;
      D : My_Integer := 0;
   end record;

   V : Record_T := (others => 1);
begin
   Put_Line (Integer'Image (V.A));
end Main;
```

A. 0
B. 1
C. Compilation error
D. Runtime error

Quiz

What is the result of building and running this code?

```
procedure Main is
   type My_Integer is new Integer;
   type Record_T is record
      A, B, C : Integer := 0;
      D : My_Integer := 0;
   end record;

   V : Record_T := (others => 1);
begin
   Put_Line (Integer'Image (V.A));
end Main;
```

A. 0
B. 1
C. ***Compilation error***
D. Runtime error

All components associated to a value using `others` must be of the same `type`.

Quiz

What is the result of building and running this code?

```
procedure Main is
   type My_Integer is new Integer;
   type Record_T is record
      A, B, C : Integer := 0;
      D : My_Integer := 0;
   end record;

   V : Record_T := (others => <>);
begin
   Put_Line (Integer'Image (V.A));
end Main;
```

A. 0
B. 1
C. Compilation error
D. Runtime error

Quiz

What is the result of building and running this code?

```
procedure Main is
   type My_Integer is new Integer;
   type Record_T is record
      A, B, C : Integer := 0;
      D : My_Integer := 0;
   end record;

   V : Record_T := (others => <>);
begin
   Put_Line (Integer'Image (V.A));
end Main;
```

A. *0*
B. 1
C. Compilation error
D. Runtime error

<> is an exception to the rule for **others**, it can apply to several components of a different type.

Quiz

What is the result of building and running this code?

```
procedure Main is
   type My_Integer is new Integer;
   type Record_T is record
      A : Integer := 0;
   end record;

   V : Record_T := (1);
begin
   Put_Line (Integer'Image (V.A));
end Main;
```

A. 0
B. 1
C. Compilation error
D. Runtime error

Quiz

What is the result of building and running this code?

```
procedure Main is
   type My_Integer is new Integer;
   type Record_T is record
      A : Integer := 0;
   end record;

   V : Record_T := (1);
begin
   Put_Line (Integer'Image (V.A));
end Main;
```

A. 0
B. 1
C. ***Compilation error***
D. Runtime error

Single-valued aggregate must use named association.

Quiz

```
type Nested_T is record
   Field : Integer := 1_234;
end record;
type Record_T is record
   One   : Integer := 1;
   Two   : Character;
   Three  : Integer := -1;
   Four  : Nested_T;
end record;
X, Y : Record_T;
Z    : constant Nested_T := (others => -1);
```

Which assignment(s) is(are) illegal?

A. `X := (1, '2', Three => 3, Four => (6))`
B. `X := (Two => '2', Four => Z, others => 5)`
C. `X := Y`
D. `X := (1, '2', 4, (others => 5))`

Quiz

```
type Nested_T is record
   Field : Integer := 1_234;
end record;
type Record_T is record
   One   : Integer := 1;
   Two   : Character;
   Three  : Integer := -1;
   Four  : Nested_T;
end record;
X, Y : Record_T;
Z    : constant Nested_T := (others => -1);
```

Which assignment(s) is(are) illegal?

A. *X := (1, '2', Three => 3, Four => (6))*
B. `X := (Two => '2', Four => Z, others => 5)`
C. `X := Y`
D. `X := (1, '2', 4, (others => 5))`

A. Four **must** use named association
B. `others` valid: `One` and `Three` are `Integer`
C. Valid but `Two` is not initialized
D. Positional for all components

Default Values

Examples

```
with Ada.Text_IO; use Ada.Text_IO;
procedure Default_Values is

   type Complex is record
      Real      : Float := -1.0;
      Imaginary : Float := -1.0;
   end record;

   Phasor : Complex;
   I      : constant Complex := (0.0, 1.0);

begin
   Put_Line
     (Float'Image (Phasor.Real) & " " & Float'Image (Phasor.Imaginary) & "i");
   Put_Line (Float'Image (I.Real) & " " & Float'Image (I.Imaginary) & "i");
   Phasor := (12.34, others => <>);
   Put_Line
     (Float'Image (Phasor.Real) & " " & Float'Image (Phasor.Imaginary) & "i");
end Default_Values;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/060_record_types.html#default-values

Component Default Values

```
type Complex is
  record
    Real : Real := 0.0;
    Imaginary : Real := 0.0;
  end record;
-- all components use defaults
Phasor : Complex;
-- all components must be specified
I : constant Complex := (0.0, 1.0);
```

Default Component Value Evaluation

- Occurs when object is elaborated
  - Not when the type is elaborated
- Not evaluated if explicitly overridden

```
type Structure is
  record
    A : Integer;
    R : Time := Clock;
  end record;
-- Clock is called for S1
S1 : Structure;
-- Clock is not called for S2
S2 : Structure := (A => 0, R => Yesterday);
```

Defaults Within Record Aggregates

Ada 2005

- Specified via the *box* notation
- Value for the component is thus taken as for a stand-alone object declaration
  - So there may or may not be a defined default!
- Can only be used with "named association" form
  - But can mix forms, unlike array aggregates

```
type Complex is
  record
    Real : Float := 0.0;
    Imaginary : Float := 0.0;
  end record;
Phase := (42.0, Imaginary => <>);
```

Default Initialization Via Aspect Clause

Ada 2012

- Not definable for entire record type
- Components of scalar types take type's default if no explicit default value specified by record type

```
type Toggle_Switch is (Off, On)
    with Default_Value => Off;
type Controller is record
    -- Off unless specified during object initialization
    Override : Toggle_Switch;
    -- default for this component
    Enable : Toggle_Switch := On;
  end record;
C : Controller; -- Override => off, Enable => On
D : Controller := (On, Off); -- All defaults replaced
```

Quiz

Ada 2012

```
function Next return Natural; -- returns next number starting with 1

type Record_T is record
   A, B : Integer := Next;
   C    : Integer := Next;
end record;
R : Record_T := (C => 100, others => <>);
```

What is the value of R?

A. (1, 2, 3)
B. (1, 1, 100)
C. (1, 2, 100)
D. (100, 101, 102)

Quiz

Ada 2012

```
function Next return Natural; -- returns next number starting with 1

type Record_T is record
   A, B : Integer := Next;
   C    : Integer := Next;
end record;
R : Record_T := (C => 100, others => <>);
```

What is the value of R?

A. (1, 2, 3)
B. (1, 1, 100)
C. ***(1, 2, 100)***
D. (100, 101, 102)

Explanations

A. `C => 100`
B. Multiple declaration calls `Next` twice
C. Correct
D. `C => 100` has no effect on `A` and `B`

Discriminated Records

Discriminated Record Types

- *Discriminated record* type
  - Different **objects** may have **different** components
  - All object **still** share the same type
- Kind of *storage overlay*
  - Similar to `union` in C
  - But preserves **type checking**
  - And object size **depends** on discriminant
- Aggregate assignment is allowed

Discriminants

```
type Person_Group is (Student, Faculty);
type Person (Group : Person_Group) is record
   Name : String (1 .. 10);
   case Group is
      when Student => -- 1st variant
         Gpa  : Float range 0.0 .. 4.0;
      when Faculty => -- 2nd variant
         Pubs : Integer;
   end case;
end record;
```

- `Group` is the *discriminant*
- Run-time check for component **consistency**
  - eg `A_Person.Pubs := 1` checks `A_Person.Group = Faculty`
  - `Constraint_Error` if check fails
- Discriminant is **constant**
  - Unless object is **mutable**

Semantics

- Person objects are **constrained** by their discriminant
  - **Unless** mutable
  - Assignment from same variant **only**
  - **Representation** requirements

```
Pat  : Person(Student); -- No Pat.Pubs
Prof : Person(Faculty); -- No Prof.GPA
Soph : Person := ( Group  => Student,
                   Name => "John Jones",
                   GPA  => 3.2);
X : Person;  -- Illegal: must specify discriminant

Pat  := Soph; -- OK
Soph := Prof; -- Constraint_Error at run time
```

Mutable Discriminated Record

- When discriminant has a **default value**
  - Objects instantiated **using the default** are **mutable**
  - Objects specifying an **explicit** value are **not** mutable
- Mutable records have **variable** discriminants
- Use **same** storage for **several** variant

```
-- Potentially mutable
type Person (Group : Person_Group := Student) is record

--  Use default value: mutable
S : Person;
--  Explicit value: *not* mutable
--  even if Student is also the default
S2 : Person (Group => Student);
...
S := (Group => Student, Gpa => 0.0);
S := (Group => Faculty, Pubs => 10);
```

Lab

Record Types Lab

- Requirements
  - Create a simple First-In/First-Out (FIFO) queue record type and object
  - Allow the user to:
    - Add ("push") items to the queue
    - Remove ("pop") the next item to be serviced from the queue (Print this item to ensure the order is correct)
  - When the user is done manipulating the queue, print out the remaining items in the queue
- Hints
  - Queue record should at least contain:
    - Array of items
    - Index into array where next item will be added

Record Types Lab Solution - Declarations

```
with Ada.Text_IO; use Ada.Text_IO;
procedure Main is

   type Name_T is array (1 .. 6) of Character;
   type Index_T is range 0 .. 1_000;
   type Queue_T is array (Index_T range 1 .. 1_000) of Name_T;

   type Fifo_Queue_T is record
      Next_Available : Index_T := 1;
      Last_Served    : Index_T := 0;
      Queue          : Queue_T := (others => (others => ' '));
   end record;

   Queue : Fifo_Queue_T;
   Choice : Integer;
```

Record Types Lab Solution - Implementation

```
begin

   loop
      Put ("1 = add to queue | 2 = remove from queue | others => done: ");
      Choice := Integer'Value (Get_Line);
      if Choice = 1 then
         Put ("Enter name: ");
         Queue.Queue (Queue.Next_Available) := Name_T (Get_Line);
         Queue.Next_Available               := Queue.Next_Available + 1;
      elsif Choice = 2 then
         if Queue.Next_Available = 1 then
            Put_Line ("Nobody in line");
         else
            Queue.Last_Served := Queue.Last_Served + 1;
            Put_Line ("Now serving: " & String (Queue.Queue (Queue.Last_Served)));
         end if;
      else
         exit;
      end if;
      New_Line;
   end loop;

   Put_Line ("Remaining in line: ");
   for Index in Queue.Last_Served + 1 .. Queue.Next_Available - 1 loop
      Put_Line ("  " & String (Queue.Queue (Index)));
   end loop;

end Main;
```

Summary

Summary

- Heterogeneous types allowed for components
- Default initial values allowed for components
  - Evaluated when each object elaborated, not the type
  - Not evaluated if explicit initial value specified
- Aggregates express literals for composite types
  - Can mix named and positional forms

Expressions

Introduction

Advanced Expressions

- Different categories of expressions above simple assignment and conditional statements
  - Constraining types to sub-ranges to increase readability and flexibility
    - Allows for simple membership checks of values
  - Embedded conditional assignments
    - Equivalent to C's `A ? B : C` and even more elaborate
  - Universal / Existential checks
    - Ability to easily determine if one or all of a set match a condition

Membership Tests

Examples

```
with Ada.Text_IO; use Ada.Text_IO;
procedure Membership_Tests is
   subtype Index_T is Integer range 1 .. 100;
   X : constant Integer := Integer (Line);
   B : Boolean          := X in 1 .. 100;
   C : Boolean          := not (X in Index_T);
   D : Boolean          := X not in Index_T;

   type Calendar_Days is (Sun, Mon, Tues, Wed, Thur, Fri, Sat);
   subtype Weekdays is Calendar_Days range Mon .. Fri;
   Day : Calendar_Days := Calendar_Days'Val (X);

begin

   if Day in Sun | Sat then
      -- identical expressions
      B   := Day in Mon .. Fri;
      C   := Day in Weekdays;
      Day := Wed;
   elsif Day = Mon or Day = Tues then
      D   := D and (B or C);
      Day := Thur;
   end if;

   Put_Line (D'Image & " " & B'Image & " " & C'Image);
   Put_Line (Day'Image);

end Membership_Tests;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/080_expressions.html#membership-tests

"Membership" Operation

- Syntax

```
simple_expression [not] in membership_choice_list
membership_choice_list ::= membership_choice
                           { | membership_choice}
membership_choice ::= expression | range | subtype_mark
```

- Acts like a boolean function
- Usable anywhere a boolean value is allowed

```
X : Integer := ...
B : Boolean := X in 0..5;
C : Boolean := X not in 0..5; -- also "not (X in 0..5)"
```

Testing Constraints via Membership

```
type Calendar_Days  is
    (Mon, Tues, Wed, Thur, Fri, Sat, Sun);
subtype Weekdays is Calendar_Days range Mon .. Fri;
Day : Calendar_Days := Today;
...
if Day in Mon .. Fri then ...
if Day in Weekdays then ... - same as above
```

Testing Non-Contiguous Membership

Ada 2012

- Uses vertical bar "choice" syntax

```
declare
 M : Month_Number := Month (Clock);
begin
  if M in 9 | 4 | 6 | 11 then
    Put_Line ("31 days in this month");
  elsif M = 2 then
    Put_Line ("It's February, who knows?");
  else
    Put_Line ("30 days in this month");
  end if;
```

Quiz

```
type Days_T is (Sun, Mon, Tue, Wed, Thu, Fri, Sat);
subtype Weekdays_T is Days_T range Mon .. Fri;
Today : Days_T;
```

Which condition is illegal?

A. `if Today = Mon or Wed or Fri then`
B. `if Today in Days_T then`
C. `if Today not in Weekdays_T then`
D. `if Today in Tue | Thu then`

Quiz

```
type Days_T is (Sun, Mon, Tue, Wed, Thu, Fri, Sat);
subtype Weekdays_T is Days_T range Mon .. Fri;
Today : Days_T;
```

Which condition is illegal?

A. `if Today = Mon or Wed or Fri then`
B. `if Today in Days_T then`
C. `if Today not in Weekdays_T then`
D. `if Today in Tue | Thu then`

Explanations

A. To use `or`, both sides of the comparison must be duplicated (e.g. `Today = Mon or Today = Wed`)
B. Legal - should always return `True`
C. Legal - returns `True` if `Today` is `Sat` or `Sun`
D. Legal - returns `True` if `Today` is `Tue` or `Thu`

Qualified Names

Qualification

- Explicitly indicates the subtype of the value
- Syntax

```
qualified_expression ::= subtype_mark'(expression) |
                         subtype_mark'aggregate
```

- Similar to conversion syntax
  - Mnemonic - "qualification uses quote"
- Various uses shown in course
  - Testing constraints
  - Removing ambiguity of overloading
  - Enhancing readability via explicitness

Testing Constraints via Qualification

- Asserts value is compatible with subtype
  - Raises exception `Constraint_Error` if not true

```
subtype Weekdays is Days range Mon .. Fri;
This_Day : Days;
...
case Weekdays'(This_Day) is --runtime error if out of range
  when Mon =>
    Arrive_Late;
    Leave_Early;
  when Tue .. Thur =>
    Arrive_Early;
    Leave_Late;
  when Fri =>
    Arrive_Early;
    Leave_Early;
end case; -- no 'others' because all subtype values covered
```

Index Constraints

- Specify bounds for unconstrained array types

```
type Vector is array (Positive range <>) of Real;
subtype Position_Vector is Vector (1..3);
V : Position_Vector;
```

- Index constraints must not already be specified

```
type String is array (Positive range <>) of Character;
subtype Full_Name is String(1 .. Max);
subtype First_Name is Full_Name(1 .. N); -- compile erro
```

Conditional Expressions

Examples

```
with Ada.Text_IO; use Ada.Text_IO;
procedure Conditional_Expressions is

   type Months_T is
     (Jan, Feb, Mar, Apr, May, Jun, Jul, Aug, Sep, Oct, Nov, Dec);
   Year : constant Integer := 2_020;

   procedure If_Expression is
      Counter : Natural := 5;
   begin
      while Counter > 0 loop
         Put_Line
           ("Self-destruct in" & Natural'Image (Counter) &
            (if Counter = 1 then " second" else " seconds"));
         delay 1.0;
         Counter := Counter - 1;
      end loop;
      Put_Line ("Boom! (goodbye Nostromo)");
   end If_Expression;

   procedure Case_Expression is
      Leap_Year : constant Boolean :=
        (Year mod 4 = 0 and Year mod 100 /= 0) or else (Year mod 400 = 0);
   begin
      for M in Months_T loop
         Put_Line
           (M'Image & " => " &
            Integer'Image
              (case M is when Sep | Apr | Jun | Nov => 30,
                 when Feb    => (if Leap_Year then 29 else 28),
                 when others => 31));
      end loop;
   end Case_Expression;

begin
   If_Expression;
   Case_Expression;
end Conditional_Expressions;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/080_expressions.html#conditional-expressions

Conditional Expressions

Ada 2012

- Ultimate value depends on a controlling condition
- Allowed wherever an expression is allowed
  - Assignment RHS, formal parameters, aggregates, etc.
- Similar intent as in other languages
  - Java, C/C++ ternary operation **A ? B : C**
  - Python conditional expressions
  - etc.
- Two forms:
  - *If expressions*
  - *Case expressions*

If Expressions

Ada 2012

- Syntax looks like an if-statement without `end if`

```
if_expression ::=
   (if condition then dependent_expression
   {elsif condition then dependent_expression}
   [else dependent_expression])
condition ::= boolean_expression
```

  - The conditions are always Boolean values

```
(if Today > Wednesday then 1 else 0)
```

Result Must Be Compatible with Context

- The **dependent_expression** parts, specifically

```
X : Integer :=
   (if Day_Of_Week (Clock) > Wednesday then 1 else 0);
```

If Expression Example

```
declare
   Remaining : Natural := 5;   -- arbitrary
begin
   while Remaining > 0 loop
      Put_Line ("Warning! Self-destruct in" &
        Remaining'Image &
        (if Remaining = 1 then " second" else " seconds"));
      delay 1.0;
      Remaining := Remaining - 1;
   end loop;
   Put_Line ("Boom! (goodbye Nostromo)");
```

Boolean If-Expressions

- Return a value of either True or False
  - `(if P then Q)` - assuming **P** and **Q** are **Boolean**
  - "If P is True then the result of the if-expression is the value of Q"
- But what is the overall result if all conditions are False?
- Answer: the default result value is True
  - Why?
    - Consistency with mathematical proving

The **else** Part When Result Is Boolean

- Redundant because the default result is True
  - `(if P then Q else True)`
- So for convenience and elegance it can be omitted

```
Acceptable : Boolean := (if P1 > 0 then P2 > 0 else True
Acceptable : Boolean := (if P1 > 0 then P2 > 0);
```

- Use `else` if you need to return False at the end

Rationale for Parentheses Requirement

- Prevents ambiguity regarding any enclosing expression
- Problem:

```
X : integer := if condition then A else B + 1;
```

- Does that mean
  - If condition, then **X := A + 1**, else **X := B + 1 OR**
  - If condition, then **X := A**, else **X := B + 1**
- But not required if parentheses already present
  - Because enclosing construct includes them

```
Subprogram_Call(if A then B else C);
```

When To Use *If Expressions*

- When you need computation to be done prior to sequence of statements
  - Allows constants that would otherwise have to be variables
- When an enclosing function would be either heavy or redundant with enclosing context
  - You'd already have written a function if you'd wanted one
- Preconditions and postconditions
  - All the above reasons
  - Puts meaning close to use rather than in package body
- Static named numbers
  - Can be much cleaner than using Boolean'Pos(condition)

If Expression Example for Constants

- Starting from

```
End_of_Month : array (Months) of Days
  := (Sep | Apr | Jun | Nov => 30,
      Feb => 28,
      others => 31);
begin
  if Leap (Today.Year) then -- adjust for leap year
    End_of_Month (Feb) := 29;
  end if;
  if Today.Day = End_of_Month(Today.Month) then
...
```

- Using if-expression to call `Leap (Year)` as needed

```
End_Of_Month : constant array (Months) of Days
  := (Sep | Apr | Jun | Nov => 30,
      Feb => (if Leap (Today.Year)
              then 29 else 28),
      others => 31);
begin
  if Today.Day /= End_of_Month(Today.Month) then
...
```

Case Expressions

Ada 2012

- Syntax similar to `case` statements
  - Lighter: no closing **end case**
  - Commas between choices
- Same general rules as *if expressions*
  - Parentheses required unless already present
  - Type of "result" must match context
- Advantage over *if expressions* is completeness checked by compiler
- Same as with `case` statements (unless `others` is used)

```
-- compile error if not all days covered
Hours : constant Integer :=
   (case Day_of_Week is
    when Mon .. Thurs => 9,
    when Fri          => 4,
    when Sat | Sun    => 0);
```

Case Expression Example

```
Leap : constant Boolean :=
   (Today.Year mod 4 = 0 and Today.Year mod 100 /= 0)
   or else
   (Today.Year mod 400 = 0);
End_Of_Month : array (Months) of Days;
...
-- initialize array
for M in Months loop
  End_Of_Month (M):=
     (case M is
      when Sep | Apr | Jun | Nov => 30,
      when Feb => (if Leap then 29 else 28),
      when others => 31);
end loop;
```

Quiz

```
function Sqrt (X : Float) return Float;
F : Float;
B : Boolean;
```

Which statement is illegal?

A. `F := if X < 0.0 then Sqrt (-1.0 * X) else Sqrt (X);`
B. `F := Sqrt( if X < 0.0 then -1.0 * X else X );`
C. `B := (if X < 0.0 then Sqrt (-1.0 * X) < 10.0 else True);`
D. `B := (if X < 0.0 then Sqrt (-1.0 * X) < 10.0);`

Quiz

```
function Sqrt (X : Float) return Float;
F : Float;
B : Boolean;
```

Which statement is illegal?

A. `F := if X < 0.0 then Sqrt (-1.0 * X) else Sqrt (X);`
B. `F := Sqrt( if X < 0.0 then -1.0 * X else X );`
C. `B := (if X < 0.0 then Sqrt (-1.0 * X) < 10.0 else True);`
D. `B := (if X < 0.0 then Sqrt (-1.0 * X) < 10.0);`

Explanations

A. Missing parentheses around expression
B. Legal - Expression is already enclosed in parentheses so you don't need to add more
C. Legal - `else True` not needed but is allowed
D. Legal - `B` will be `True` if X $>=$ 0.0

Lab

Expressions Lab

- Requirements
  - Allow the user to fill a list with dates
  - After the list is created, create functions to print True/False if ...
    - Any date is not legal (taking into account leap years!)
    - All dates are in the same calendar year
  - Use *expression functions* for all validation routines
- Hints
  - Use subtype membership for range validation
  - You will need *conditional expressions* in your functions
  - You *can* use component-based iterations for some checks
    - But you *must* use indexed-based iterations for others

Expressions Lab Solution - Checks

```
subtype Year_T is Positive range 1_900 .. 2_099;
subtype Month_T is Positive range 1 .. 12;
subtype Day_T is Positive range 1 .. 31;

type Date_T is record
   Year  : Positive;
   Month : Positive;
   Day   : Positive;
end record;

List : array (1 .. 5) of Date_T;
Item : Date_T;

function Is_Leap_Year (Year : Positive)
                       return Boolean is
  (Year mod 400 = 0 or else (Year mod 4 = 0 and Year mod 100 /= 0));

function Days_In_Month (Month : Positive;
                        Year  : Positive)
                        return Day_T is
  (case Month is when 4 | 6 | 9 | 11 => 30,
     when 2 => (if Is_Leap_Year (Year) then 29 else 28), when others => 31);

function Is_Valid (Date : Date_T)
                   return Boolean is
  (Date.Year in Year_T and then Date.Month in Month_T
   and then Date.Day <= Days_In_Month (Date.Month, Date.Year));

function Any_Invalid return Boolean is
begin
   for Date of List loop
      if not Is_Valid (Date) then
         return True;
      end if;
   end loop;
   return False;
end Any_Invalid;

function Same_Year return Boolean is
begin
   for Index in List'range loop
      if List (Index).Year /= List (List'first).Year then
         return False;
      end if;
   end loop;
   return True;
end Same_Year;
```

Expressions Lab Solution - Main

```
   function Number (Prompt : String)
                    return Positive is
   begin
      Put (Prompt & "> ");
      return Positive'Value (Get_Line);
   end Number;

begin

   for I in List'Range loop
      Item.Year  := Number ("Year");
      Item.Month := Number ("Month");
      Item.Day   := Number ("Day");
      List (I)   := Item;
   end loop;

   Put_Line ("Any invalid: " & Boolean'image (Any_Invalid));
   Put_Line ("Same Year: " & Boolean'image (Same_Year));

end Main;
```

Summary

Summary

- Conditional expressions are allowed wherever expressions are allowed, but beware over-use
  - Especially useful when a constant is intended
  - Especially useful when a static expression is required

Quantified Expressions

Quantified Expressions

Introduction

Ada 2012

- Expressions that have a Boolean value
- The value indicates something about a set of objects
  - In particular, whether something is True about that set
- That "something" is expressed as an arbitrary boolean expression
  - A so-called "predicate"
- "Universal" quantified expressions
  - Indicate whether predicate holds for all components
- "Existential" quantified expressions
  - Indicate whether predicate holds for at least one component

Examples

```
with GNAT.Random_Numbers; use GNAT.Random_Numbers;
with Ada.Text_IO;         use Ada.Text_IO;
procedure Quantified_Expressions is
   Gen    : Generator;
   Values : constant array (1 .. 10) of Integer := (others => Random (Gen));

   Any_Even : constant Boolean := (for some N of Values => N mod 2 = 0);
   All_Odd  : constant Boolean := (for all N of reverse Values => N mod 2 = 1);

   function Is_Sorted return Boolean is
     (for all K in Values'Range =>
        K = Values'First or else Values (K - 1) <= Values (K));

   function Duplicate return Boolean is
     (for some I in Values'Range =>
        (for some J in I + 1 .. Values'Last => Values (I) = Values (J)));

begin
   Put_Line ("Any Even: " & Boolean'Image (Any_Even));
   Put_Line ("All Odd: " & Boolean'Image (All_Odd));
   Put_Line ("Is_Sorted " & Boolean'Image (Is_Sorted));
   Put_Line ("Duplicate " & Boolean'Image (Duplicate));
end Quantified_Expressions;
```

Semantics Are As If You Wrote This Code

Ada 2012

```
function Universal (Set : Components) return Boolean is
begin
  for C of Set loop
    if not Predicate (C) then
      return False;  -- Predicate must be true for all
    end if;
  end loop;
  return True;
end Universal;

function Existential (Set : Components) return Boolean is
begin
  for C of Set loop
    if Predicate (C) then
      return True;  -- Predicate need only be true for one
    end if;
  end loop;
  return False;
end Existential;
```

Quantified Expressions Syntax

Ada 2012

- Four `for` variants
  - Index-based `in` or component-based `of`
  - Existential `some` or universal `all`
- Using arrow => to indicate *predicate* expression

```
(for some Index in Subtype_T => Predicate (Index))
(for all Index in Subtype_T => Predicate (Index))
(for some Value of Container_Obj => Predicate (Value))
(for all Value of Container_Obj => Predicate (Value))
```

Simple Examples

Ada 2012

```
Values : constant array (1 .. 10) of Integer := (...);
Is_Any_Even : constant Boolean :=
   (for some V of Values => V mod 2 = 0);
Are_All_Even : constant Boolean :=
   (for all V of Values => V mod 2 = 0);
```

Universal Quantifier

Ada 2012

- In logic, denoted by $\forall$ (inverted 'A', for "all")
- "There is no member of the set for which the predicate does not hold"
  - If predicate is False for any member, the whole is False
- Functional equivalent

```
function Universal (Set : Components) return Boolean is
begin
   for C of Set loop
      if not Predicate (C) then
         return False; -- Predicate must be true for all
      end if;
   end loop;
   return True;
end Universal;
```

Universal Quantifier Illustration

Ada 2012

- "There is no member of the set for which the predicate does not hold"
- Given a set of integer answers to a quiz, there are no answers that are not 42 (i.e., all are 42)

```
Ultimate_Answer : constant := 42; -- to everything...
Answers : constant array (1 .. 10)
    of Integer := ( ... );
All_Correct_1 : constant Boolean :=
   (for all Component of Answers =>
      Component = Ultimate_Answer);
All_Correct_2 : constant Boolean :=
   (for all K in Answers'range =>
      Answers(K) = Ultimate_Answer);
```

Universal Quantifier Real-World Example

Ada 2012

```
type DMA_Status_Flag is ( ... );
function Status_Indicated (
  Flag : DMA_Status_Flag)
  return Boolean;
None_Set : constant Boolean := (
  for all Flag in DMA_Status_Flag =>
    not Status_Indicated (Flag));
```

Existential Quantifier

Ada 2012

- In logic, denoted by ∃ (rotated 'E', for "exists")
- "There is at least one member of the set for which the predicate holds"
  - If predicate is True for any member, the whole is True
- Functional equivalent

```
function Existential (Set : Components) return Boolean is
begin
   for C of Set loop
      if Predicate (C) then
         return True; -- Need only be true for at least one
      end if;
   end loop;
   return False;
end Existential;
```

Existential Quantifier Illustration

Ada 2012

- "There is at least one member of the set for which the predicate holds"
- Given set of integer answers to a quiz, there is at least one answer that is 42

```
Ultimate_Answer : constant := 42; -- to everything...
Answers : constant array (1 .. 10)
    of Integer := ( ... );
Any_Correct_1 : constant Boolean :=
   (for some Component of Answers =>
      Component = Ultimate_Answer);
Any_Correct_2 : constant Boolean :=
   (for some K in Answers'range =>
      Answers(K) = Ultimate_Answer);
```

Index-Based vs Component-Based Indexing

Ada 2012

- Given an array of integers

```
Values : constant array (1 .. 10) of Integer := (...);
```

- Component-based indexing is useful for checking individual values

```
Contains_Negative_Number : constant Boolean :=
   (for some N of Values => N < 0);
```

- Index-based indexing is useful for comparing across values

```
Is_Sorted : constant Boolean :=
  (for all I in Values'Range =>
    I = Values'first or else Values(I) >= Values(I-1));
```

"Pop Quiz" for Quantified Expressions

Ada 2012

- What will be the value of **Ascending_Order**?

```
Table : constant array (1 .. 10) of Integer :=
      (1, 2, 3, 4, 5, 6, 7, 8, 9, 10);
Ascending_Order : constant Boolean := (
  for all K in Table'Range =>
    K > Table'First and then Table (K - 1) <= Table (K));
```

  - Answer: **False**. Predicate fails when **K = Table'First**
    - First subcondition is False!
    - Condition should be

```
Ascending_Order : constant Boolean := (
   for all K in Table'Range =>
      K = Table'first or else Table (K - 1) <= Table (K));
```

When The Set Is Empty...

Ada 2012

- Universally quantified expressions are True
  - Definition: there is no member of the set for which the predicate does not hold
  - If the set is empty, there is no such member, so True
  - "All people 12-feet tall will be given free chocolate."
- Existentially quantified expressions are False
  - Definition: there is at least one member of the set for which the predicate holds
- If the set is empty, there is no such member, so False
- Common convention in set theory, arbitrary but settled

Not Just Arrays: Any "Iterable" Objects

Ada 2012

- Those that can be iterated over
- Language-defined, such as the containers
- User-defined too

```
package Characters is new
   Ada.Containers.Vectors (Positive, Character);
use Characters;
Alphabet  : constant Vector := To_Vector('A',1) & 'B' & 'C';
Any_Zed   : constant Boolean :=
             (for some C of Alphabet => C = 'Z');
All_Lower : constant Boolean :=
              (for all C of Alphabet => Is_Lower (C));
```

Conditional / Quantified Expression Usage

Ada 2012

- Use them when a function would be too heavy
- Don't over-use them!

```
if (for some Component of Answers =>
     Component = Ultimate_Answer)
then
```

- Function names enhance readability
  - So put the quantified expression in a function

```
if At_Least_One_Answered (Answers) then
```

- Even in pre/postconditions, use functions containing quantified expressions for abstraction

Quiz

Which declaration(s) is(are) legal?

A.
```
function F (S : String) return Boolean is
  (for all C of S => C /= ' ');
```

B.
```
function F (S : String) return Boolean is
  (not for some C of S => C = ' ');
```

C.
```
function F (S : String) return String is
  (for all C of S => C);
```

D.
```
function F (S : String) return String is
  (if (for all C of S => C /= ' ') then "OK"
   else "NOK");
```

Quiz

Which declaration(s) is(are) legal?

A.
```
function F (S : String) return Boolean is
  (for all C of S => C /= ' ');
```

B.
```
function F (S : String) return Boolean is
  (not for some C of S => C = ' ');
```

C.
```
function F (S : String) return String is
  (for all C of S => C);
```

D.
```
function F (S : String) return String is
  (if (for all C of S => C /= ' ') then "OK"
   else "NOK");
```

B. Parentheses required around the quantified expression

C. Must return a `Boolean`

Quiz

```
type T1 is array (1 .. 3) of Integer;
type T2 is array (1 .. 3) of Integer;
```

Which piece(s) of code correctly perform(s) equality check on A and B?

A.
```
function "=" (A : T1; B : T2) return Boolean is
   (A = T1 (B));
```

B.
```
function "=" (A : T1; B : T2) return Boolean is
   (for all E1 of A => (for all E2 of B => E1 = E2));
```

C.
```
function "=" (A : T1; B : T2) return Boolean is
   (for some E1 of A => (for some E2 of B => A = B));
```

D.
```
function "=" (A : T1; B : T2) return Boolean is
   (for all J in A'Range => A (J) = B (J));
```

Quiz

```
type T1 is array (1 .. 3) of Integer;
type T2 is array (1 .. 3) of Integer;
```

Which piece(s) of code correctly perform(s) equality check on A and B?

A.
```
function "=" (A : T1; B : T2) return Boolean is
   (A = T1 (B));
```

B.
```
function "=" (A : T1; B : T2) return Boolean is
   (for all E1 of A => (for all E2 of B => E1 = E2));
```

C.
```
function "=" (A : T1; B : T2) return Boolean is
   (for some E1 of A => (for some E2 of B => A = B));
```

D.
```
function "=" (A : T1; B : T2) return Boolean is
   (for all J in A'Range => A (J) = B (J));
```

B. Counterexample: `A = B = (0, 1, 0)` returns `False`

C. Counterexample: `A = (0, 0, 1)` and `B = (0, 1, 1)` returns `True`

Quiz

```
type Array1_T is array (1 .. 3) of Integer;
type Array2_T is array (1 .. 3) of Array1_T;
A : Array2_T;
```

The above describes an array A whose elements are arrays of three elements. Which expression would one use to determine if at least one of A's elements are sorted?

A.
```
(for some El of A => (for some Idx in 2 .. 3 =>
   El (Idx) >= El (Idx - 1)));
```

B.
```
(for all El of A => for all Idx in 2 .. 3 =>
   El (Idx) >= El (Idx - 1)));
```

C.
```
(for some El of A => (for all Idx in 2 ..  3 =>
   El (Idx) >= El (Idx - 1)));
```

D.
```
(for all El of A => (for some Idx in 2 .. 3 =>
    El (Idx) >= El (Idx - 1)));
```

Quiz

```
type Array1_T is array (1 .. 3) of Integer;
type Array2_T is array (1 .. 3) of Array1_T;
A : Array2_T;
```

The above describes an array A whose elements are arrays of three elements. Which expression would one use to determine if at least one of A's elements are sorted?

A.
```
(for some El of A => (for some Idx in 2 .. 3 =>
   El (Idx) >= El (Idx - 1)));
```

B.
```
(for all El of A => for all Idx in 2 .. 3 =>
   El (Idx) >= El (Idx - 1)));
```

C.
```
(for some El of A => (for all Idx in 2 ..  3 =>
   El (Idx) >= El (Idx - 1)));
```

D.
```
(for all El of A => (for some Idx in 2 .. 3 =>
    El (Idx) >= El (Idx - 1)));
```

A. Will be `True` if any element has two consecutive increasing values
B. Will be `True` if every element is sorted
C. Correct
D. Will be `True` if every element has two consecutive increasing values

Lab

Advanced Expressions Lab

- Requirements
  - Allow the user to fill a list with dates
  - After the list is created, use *quantified expressions* to print True/False
    - If any date is not legal (taking into account leap years!)
    - If all dates are in the same calendar year
  - Use *expression functions* for all validation routines
- Hints
  - Use subtype membership for range validation
  - You will need *conditional expressions* in your functions
  - You *can* use component-based iterations for some checks
    - But you *must* use indexed-based iterations for others
  - This is the same lab as the *Expressions* lab, we're just replacing the validation functions with quantified expressions!
    - So you can just copy that project and update the code!

Advanced Expressions Lab Solution - Checks

```
subtype Year_T is Positive range 1_900 .. 2_099;
subtype Month_T is Positive range 1 .. 12;
subtype Day_T is Positive range 1 .. 31;

type Date_T is record
   Year  : Positive;
   Month : Positive;
   Day   : Positive;
end record;

List : array (1 .. 5) of Date_T;
Item : Date_T;

function Is_Leap_Year (Year : Positive)
                       return Boolean is
  (Year mod 400 = 0 or else (Year mod 4 = 0 and Year mod 100 /= 0));

function Days_In_Month (Month : Positive;
                        Year  : Positive)
                        return Day_T is
  (case Month is when 4 | 6 | 9 | 11 => 30,
     when 2 => (if Is_Leap_Year (Year) then 29 else 28), when others => 31);

function Is_Valid (Date : Date_T)
                   return Boolean is
  (Date.Year in Year_T and then Date.Month in Month_T
   and then Date.Day <= Days_In_Month (Date.Month, Date.Year));

function Any_Invalid return Boolean is
  (for some Date of List => not Is_Valid (Date));

function Same_Year return Boolean is
  (for all I in List'range => List (I).Year = List (List'first).Year);
```

Advanced Expressions Lab Solution - Main

```
   function Number (Prompt : String)
                    return Positive is
   begin
      Put (Prompt & "> ");
      return Positive'Value (Get_Line);
   end Number;

begin

   for I in List'Range loop
      Item.Year  := Number ("Year");
      Item.Month := Number ("Month");
      Item.Day   := Number ("Day");
      List (I)   := Item;
   end loop;

   Put_Line ("Any invalid: " & Boolean'image (Any_Invalid));
   Put_Line ("Same Year: " & Boolean'image (Same_Year));

end Main;
```

Summary

Summary

- Quantified expressions are general purpose but especially useful with pre/postconditions
  - Consider hiding them behind expressive function names

Annex - GNAT options

Understanding the GNAT Build Steps

- **gcc** is responsible to compile source files into object files
  - package **Compiler** of the gpr file
- **gnatbind** is responsible to schedule the elaboration of all units
  - package **Binder** of the gpr file
- **gnatlink** is responsible for linking the application into one executable / library
  - package **Linker** of the gpr file
- **gprbuild** is responsible of calling these tools

Targets and Runtimes

- Most tools have a "native" name (gcc, gnat, gnatcheck, etc.)
- The name of the tool for the target is "**target-toolname**"
  - powerpc-wrs-vxworksae-gcc
  - powerpc-wrs-vxworksae-gnatcheck
- Exceptions: gnatstack, gprbuild, gnatstudio
- The runtime is introduced with the --**RTS=** switch
  - powerpc-wrs-vxworksae-gcc --RTS=zfp

Some useful GNAT switches

- **-O[0,1,2,3,s]**
  - Turns optimizations (0 = Minimal, 3 = Maximal, s = optimize for size)
- **-g**
  - Turn on debug information
- **-c**
  - Only compile (do not build)
- **-gnatc**
  - Do only semantic analysis (do not generate code)
- **-gnatn**
  - Activates `pragma Inline`
- **-gnata**
  - Activates assertions
- **-gnateE**
  - Extends messages produced for run-time checks
- **-gnatp**
  - Removes run-time checks

Validity checks

- **-gnatV[x]** options add checks on values validity
- Checks if variables have an expected value in a lot of places
- Expensive test (this is why it's not added by default)
- `pragma Normalize_Scalar`
  - Makes sure that uninitialized variables are initialized with invalid default

Data representation

- **-gnatDG** produces *filename.dg* representing the intermediate representation
- Code is expanded into simple structures and system calls
- Useful to understand the complexity of the Ada constructions
- Useful to identify check locations
- Integrated into GNAT Studio

Intermediate representation

- `-gnatR#` displays representations of

0	None
1	Type
2	All
3	Variable

  - Helps optimizing data structures

- `-gnatR1`

```
type Rec1 is record
   A : Boolean;
   B : Integer;
   C : Boolean;
end record;
for Rec1'Object_Size use 9
for Rec1'Value_Size use 72
for Rec1'Alignment use 4;
for Rec1 use record
   A at 0 range  0 ..  7;
   B at 4 range  0 .. 31;
   C at 8 range  0 ..  7;
end record;
```

Intermediate representation (cont)

- -gnatR2

```
type Rec2 is record
   A : Boolean;
   C : Boolean;
   B : Integer;
end record;
for Rec2'Size use 64;
for Rec2'Alignment use 4;
for Rec2 use record
   A at 0 range  0 ..  7;
   C at 1 range  0 ..  7;
   B at 4 range  0 .. 31;
end record;
```

- -gnatR3

```
type Rec3 is record
   A : Boolean;
   B : Integer;
   C : Boolean;
end record;
pragma Pack (Rec3);
for Rec3'Object_Size use 40
for Rec3'Value_Size use 34
for Rec3'Alignment use 1;
for Rec3 use record
   A at 0 range  0 ..  0;
   B at 0 range  1 .. 32;
   C at 4 range  1 ..  1;
end record;
```

Inlining

- Must be activated through **-gnatn**
- Subprograms are selected through `pragma Inline`
- Dependencies need visibility on the body (inlining works cross unit)
- **gnatcheck** can flag wrong (too complex) inlining

Some Additional Tools

- **gprclean**
  - Removes all compilation products (.o, .ali, .exe files)
- **gnatstub**
  - Generates a package body given a package declaration
- **gnatls**
  - Library browser
- **gnatprep**
  - Integrated preprocessor
- Many more dedicated tools for static and dynamic analysis of the program

Subprograms

Introduction

Introduction

- Are syntactically distinguished as `function` and `procedure`
  - Functions represent *values*
  - Procedures represent *actions*

```
function Is_Leaf (T : Tree) return Boolean
procedure Split (T : in out Tree;
                 Left : out Tree;
                 Right : out Tree)
```

- Provide direct syntactic support for separation of specification from implementation

```
function Is_Leaf (T : Tree) return Boolean;
function Is_Leaf (T : Tree) return Boolean is
begin
...
end Is_Leaf;
```

Recognizing Procedures and Functions

- Functions' results must be treated as values
  - And cannot be ignored
- Procedures cannot be treated as values
- You can always distinguish them via the call context

```
10  Open (Source, "SomeFile.txt");
11  while not End_of_File (Source) loop
12    Get (Next_Char, From => Source);
13    if Found (Next_Char, Within => Buffer) then
14      Display (Next_Char);
15    end if;
16  end loop;
```

A Little "Preaching" About Names

- Procedures are abstractions for actions
- Functions are abstractions for values
- Use names that reflect those facts!
  - Imperative verbs for procedure names
  - Nouns for function names, as for mathematical functions
    - Questions work for boolean functions

```
procedure Open (V : in out Valve);
procedure Close (V : in out Valve);
function Square_Root (V: Real) return Real;
function Is_Open (V: Valve) return Boolean;
```

Syntax

Specification and Body

- Subprogram specification is the external (user) **interface**
  - **Declaration** and **specification** are used synonymously
- Specification may be required in some cases
  - eg. recursion
- Subprogram body is the **implementation**

Procedure Specification Syntax (Simplified)

```
procedure Swap (A, B : in out Integer);
```

```
procedure_specification ::=
   procedure program_unit_name
     ( parameter_specification
     { ; parameter_specification} );

parameter_specification ::=
   identifier_list : mode subtype_mark [ := expression ]

mode ::= [in] | out | in out
```

Function Specification Syntax (Simplified)

```
function F (X : Real) return Real;
```

- Close to **procedure** specification syntax
  - With **return**
  - Can be an operator: + - * / **mod** **rem** ...

```
function_specification ::=
   function designator
     ( parameter_specification
     { ; parameter_specification} )
     return result_type;

designator ::= program_unit_name | operator_symbol
```

Body Syntax

```
subprogram_specification is
   [declarations]
begin
   sequence_of_statements
end [designator];
```

```
procedure Hello is
begin
   Ada.Text_IO.Put_Line ("Hello World!");
   Ada.Text_IO.New_Line (2);
end Hello;
```

```
function F (X : Real) return Real is
   Y : constant Real := X + 3.0;
begin
   return X * Y;
end F;
```

Completions

- Bodies **complete** the specification
  - There are **other** ways to complete
- Separate specification is **not required**
  - Body can act as a specification
- A declaration and its body must **fully** conform
  - Mostly **semantic** check
  - But parameters **must** have same name

```
procedure P (J, K : Integer)
procedure P (J : Integer; K : Integer)
procedure P (J, K : in Integer)
-- Invalid
procedure P (A : Integer; B : Integer)
```

Completion Examples

- Specifications

```
procedure Swap (A, B : in out Integer);
function Min (X, Y : Person) return Person;
```

- Completions

```
procedure Swap (A, B : in out Integer) is
  Temp : Integer := A;
begin
  A := B;
  B := Temp;
end Swap;

-- Completion as specification
function Less_Than ( X, Y : Person) return boolean is
begin
   return X.Age < Y.Age;
endf Less_Than

function Min (X, Y : Person) return Person;
begin
   if Less_Than ( X, Y ) then
      return X;
   else
      return Y;
   end if;
end Min;
```

Direct Recursion - No Declaration Needed

- When `is` is reached, the subprogram becomes **visible**
  - It can call **itself** without a declaration

```
type List is array (Natural range <>) of Integer;
Empty_List : constant List (1 .. 0) := (others => 0);

function Get_List return List is
  Next : Integer;
begin
  Get (Next);

  if Next = 0 then
    return Empty_List;
  else
    return Get_List & Next;
  end if;
end Input;
```

Indirect Recursion Example

- Elaboration in **linear order**

```
procedure P;

procedure F is
begin
   P;
end F;

procedure P is
begin
   F;
end P;
```

Quiz

Which profile is semantically different from the others?

A. `procedure P ( A : Integer; B : Integer );`
B. `procedure P ( A, B : Integer );`
C. `procedure P ( B : Integer; A : Integer );`
D. `procedure P ( A : in Integer; B : in Integer );`

Quiz

Which profile is semantically different from the others?

A. `procedure P ( A : Integer; B : Integer );`
B. `procedure P ( A, B : Integer );`
C. *`procedure P ( B : Integer; A : Integer );`*
D. `procedure P ( A : in Integer; B : in Integer );`

Parameter names are important in Ada. The other selections have the names in the same order with the same mode and type.

Parameters

Examples

```
procedure Parameters is

   procedure Do_Something (Formal_I : in Integer; Formal_B : out Boolean) is
   begin
      Formal_B := Formal_I > 0;
   end Do_Something;

   procedure All_Modes (Number : in     Integer;
                        Value  : in out Integer;
                        Result :    out Boolean) is
   begin
      Value  := Value * Number;
      Result := Value > 0;
   end All_Modes;

   procedure Defaults (A : Integer := 1;
                       B : Integer := 2;
                       C : Boolean := True;
                       D : Boolean := False) is null;

   type Vector is array (Positive range <>) of Float;
   procedure Add (Left : in out Vector; Right : Vector) is
   begin
      for I in Left'First .. Left'Last loop
         Left (I) := Left (I) + Right (I);
      end loop;
   end Add;

   Actual_I1, Actual_I2 : Integer := 0;
   Actual_B             : Boolean;
   Actual_V             : Vector (1 .. 100);

begin
   Do_Something (Actual_I1,
                 Formal_B => Actual_B);
   All_Modes (Actual_I1 + 100, Actual_I2, Actual_B);
   -- All_Modes (Actual_I1, Actual_I2 + 100, Actual_B); -- compile error
   Defaults (1, 2, True, False);
   Defaults;
   -- Defaults (1, True); -- compile error
   Defaults (A => 1,
             D => True);
   Add (Actual_V (1 .. 10), Actual_V (11 .. 20));
end Parameters;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/070_subprograms.html#parameters

Subprogram Parameter Terminology

- *Actual parameters* are values passed to a call
  - Variables, constants, expressions
- *Formal parameters* are defined by specification
  - Receive the values passed from the actual parameters
  - Specify the types required of the actual parameters
  - Type **cannot** be anonymous

```
procedure Something (Formal1 : in Integer);

ActualX : Integer;
...
Something (ActualX);
```

Parameter Associations In Calls

- Associate formal parameters with actuals
- Both positional and named association allowed

```
Something (ActualX, Formal2 => ActualY);
Something (Formal2 => ActualY, Formal1 => ActualX);
```

- Having named **then** positional is forbidden

```
-- Compilation Error
Something (Formal1 => ActualX, ActualY);
```

Actual Parameters Respect Constraints

- Must satisfy any constraints of formal parameters
- `Constraint_Error` otherwise

```
declare
   Q : Integer := ...
   P : Positive := ...
   procedure Foo (This : Positive);
begin
   Foo (Q); -- runtime error if Q <= 0
   Foo (P);
```

Parameter Modes and Return

- Mode `in`
  - Actual parameter is `constant`
  - Can have **default**, used when **no value** is provided

```
procedure P (N : in Integer := 1; M : in Positive);
[...]
P (M => 2);
```

- Mode `out`
  - Writing is **expected**
  - Reading is **allowed**
  - Actual **must** be a writable object
- Mode `in out`
  - Actual is expected to be **both** read and written
  - Actual **must** be a writable object
- Function `return`
  - **Must** always be handled

Why Read Mode **out** Parameters?

- **Convenience** of writing the body
  - No need for readable temporary variable
- Warning: initial value is **not defined**

```
procedure Compute (Value : out Integer) is
begin
   Value := 0;
   for K in 1 .. 10 loop
      Value := Value + K; -- this is a read AND a write
   end loop;
end Compute;
```

Parameter Passing Mechanisms

- *By-Copy*
  - The formal denotes a separate object from the actual
  - `in`, `in out`: actual is copied into the formal **on entry to** the subprogram
  - `out`, `in out`: formal is copied into the actual **on exit from** the subprogram
- *By-Reference*
  - The formal denotes a view of the actual
  - Reads and updates to the formal directly affect the actual
  - More efficient for large objects
- Parameter **types** control mechanism selection
  - Not the parameter **modes**
  - Compiler determines the mechanism

By-Copy vs By-Reference Types

- By-Copy
  - Scalar types
  - `access` types
- By-Reference
  - `tagged` types
  - `task` types and `protected` types
  - `limited` types
- `array`, `record`
  - By-Reference when they have by-reference **components**
  - By-Reference for **implementation-defined** optimizations
  - By-Copy otherwise
- `private` depends on its full definition

Unconstrained Formal Parameters or Return

- Unconstrained **formals** are allowed
  - Constrained by **actual**
- Unconstrained `return` is allowed too
  - Constrained by the **returned object**

```
type Vector is array (Positive range <>) of Real;
procedure Print (Formal : Vector);

Phase : Vector (X .. Y);
State : Vector (1 .. 4);
...
begin
   Print (Phase);           -- Formal'Range is X .. Y
   Print (State);           -- Formal'Range is 1 .. 4
   Print (State (3 .. 4)); -- Formal'Range is 3 .. 4
```

Unconstrained Parameters Surprise

- Assumptions about formal bounds may be **wrong**

```
type Vector is array (Positive range <>) of Real;
function Subtract (Left, Right : Vector) return Vector;

V1 : Vector (1 .. 10); -- length = 10
V2 : Vector (15 .. 24); -- length = 10
R : Vector (1 .. 10); -- length = 10
...
-- What are the indices returned by Subtract?
R := Subtract (V2, V1);
```

Naive Implementation

- **Assumes** bounds are the same everywhere
- Fails when `Left'First /= Right'First`
- Fails when `Left'First /= 1`

```
function Subtract (Left, Right : Vector)
  return Vector is
   Result : Vector (1 .. Left'Length);
begin
   ...
   for K in Result'Range loop
     Result (K) := Left (K) - Right (K);
   end loop;
```

Correct Implementation

- Covers **all** bounds
- `return` indexed by `Left'Range`

```
function Subtract (Left, Right : Vector) return Vector is
   Result : Vector (Left'Range);
   Offset : constant Integer := Right'First - Result'First;
begin
   ...
   for K in Result'Range loop
     Result (K) := Left (K) - Right (K + Offset);
   end loop;
```

Quiz

```
function F (P1 : in     Integer   := 0;
            P2 : in out Integer;
            P3 : in     Character := ' ';
            P4 :    out Character)
   return Integer;
J1, J2 : Integer;
C : Character;
```

Which call is legal?

A. `J1 := F (P1 => 1, P2 => J2, P3 => '3', P4 => '4');`
B. `J1 := F (P1 => 1, P3 => '3', P4 => C);`
C. `J1 := F (1, J2, '3', C);`
D. `F (J1, J2, '3', C);`

Quiz

```
function F (P1 : in     Integer   := 0;
            P2 : in out Integer;
            P3 : in     Character := ' ';
            P4 :    out Character)
   return Integer;
J1, J2 : Integer;
C : Character;
```

Which call is legal?

A. `J1 := F (P1 => 1, P2 => J2, P3 => '3', P4 => '4');`
B. `J1 := F (P1 => 1, P3 => '3', P4 => C);`
C. *`J1 := F (1, J2, '3', C);`*
D. `F (J1, J2, '3', C);`

Explanations

A. P4 is `out`, it **must** be a variable
B. P2 has no default value, it **must** be specified
C. Correct
D. `F` is a function, its `return` **must** be handled

Null Procedures

Null Procedure Declarations

Ada 2005

- Shorthand for a procedure body that does nothing
- Longhand form

```
procedure NOP is
begin
   null;
end NOP;
```

- Shorthand form

```
procedure NOP is null;
```

- The `null` statement is present in both cases
- Explicitly indicates nothing to be done, rather than an accidental removal of statements

Null Procedures As Completions

Ada 2005

- Completions for a distinct, prior declaration

```
procedure NOP;
...
procedure NOP is null;
```

- A declaration and completion together
  - A body is then not required, thus not allowed

```
procedure NOP is null;
...
procedure NOP is -- compile error
begin
   null;
end NOP;
```

Typical Use for Null Procedures: OOP

Ada 2005

- When you want a method to be concrete, rather than abstract, but don't have anything for it to do
  - The method is then always callable, including places where an abstract routine would not be callable
  - More convenient than full null-body definition

Null Procedure Summary

Ada 2005

- Allowed where you can have a full body
  - Syntax is then for shorthand for a full null-bodied procedure
- Allowed where you can have a declaration!
  - Example: package declarations
  - Syntax is shorthand for both declaration and completion
    - Thus no body required/allowed
- Formal parameters are allowed

```
procedure Do_Something ( P : in     integer ) is null;
```

Nested Subprograms

Subprograms within Subprograms

- Subprograms can be placed in any declarative block
  - So they can be nested inside another subprogram
  - Or even within a `declare` block
- Useful for performing sub-operations without passing parameter data

Nested Subprogram Example

```
1  procedure Main is
2
3     function Read (Prompt : String) return Types.Line_T is
4     begin
5        Put ("> ");
6        return Types.Line_T'Value (Get_Line);
7     end Read;
8
9     Lines : Types.Lines_T (1 .. 10);
10 begin
11    for J in Lines'Range loop
12       Lines (J) := Read ("Line " & J'Image);
13    end loop;
```

Procedure Specifics

Return Statements In Procedures

- Returns immediately to caller
- Optional
  - Automatic at end of body execution
- Fewer is traditionally considered better

```
procedure P is
begin
   ...
   if Some_Condition then
     return; -- early return
   end if;
   ...
end P; -- automatic return
```

Function Specifics

Return Statements In Functions

- Must have at least one
  - Compile-time error otherwise
  - Unless doing machine-code insertions
- Returns a value of the specified (sub)type
- Syntax

```
function defining_designator [formal_part]
      return subtype_mark is
   declarative_part
   begin
      {statements}
      return expression;
   end designator;
```

No Path Analysis Required By Compiler

- Running to the end of a function without hitting a `return` statement raises `Program_Error`
- Compilers can issue warning if they suspect that a `return` statement will not be hit

```
function Greater (X, Y : Integer) return Boolean is
begin
   if X > Y then
      return True;
   end if;
end Greater; -- possible compile warning
```

Multiple Return Statements

- Allowed
- Sometimes the most clear

```
function Truncated (R : Real) return Integer is
   Converted : Integer := Integer (R);
begin
   if R - Real (Converted) < 0.0 then -- rounded up
      return Converted - 1;
   else -- rounded down
      return Converted;
   end if;
end Truncated;
```

Multiple Return Statements Versus One

- Many can detract from readability
- Can usually be avoided

```
function Truncated (R : Real) return Integer is
   Result : Integer := Integer (R);
begin
   if R - Real (Result) < 0.0 then -- rounded up
      Result := Result - 1;
   end if;
   return Result;
end Truncated;
```

Composite Result Types Allowed

```
function Identity (Order : Positive := 3) return Matrix is
  Result : Matrix (1 .. Order, 1 .. Order);
begin
  for K in 1 .. Order loop
    for J in 1 .. Order loop
      if K = J then
        Result (K,J) := 1.0;
      else
        Result (K,J) := 0.0;
      end if;
    end loop;
  end loop;
  return Result;
end Identity;
```

Function Dynamic-Size Results

```
is
   function Char_Mult (C : Character; L : Natural)
     return String is
      R : String (1 .. L) := (others => C);
   begin
      return R;
   end Char_Mult;

   X : String := Char_Mult ('x', 4);
begin
   -- OK
   pragma Assert (X'Length = 4 and X = "xxxx");
```

Expression Functions

Examples

```
with Ada.Text_IO; use Ada.Text_IO;
procedure Expression_Functions is

   function Square1 (X : Integer) return Integer is (X * 2);
   function Square2 (X : Integer) return Integer is
   begin
      return X * 2;
   end Square2;

   function Square3 (X : Integer) return Integer;
   function Square3 (X : Integer) return Integer is (X * 2);

   function Square4 (X : Integer) return Integer is (X * 2);
   -- illegal: Square4 already complete function Square4 (X : Integer) return
   -- Integer is begin
   --    return X * 2;
   -- end Square4;

begin
   Put_Line (Integer'Image (Square1 (2)));
   Put_Line (Integer'Image (Square2 (3)));
   Put_Line (Integer'Image (Square3 (4)));
   Put_Line (Integer'Image (Square4 (5)));
end Expression_Functions;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/070_subprograms.html#expression-functions

Expression Functions

Ada 2012

- Functions whose implementations are pure expressions
  - No other completion is allowed
  - No `return` keyword
- May exist only for sake of pre/postconditions

```
function function_specification is ( expression );
```

NB: Parentheses around expression are **required**

- Can complete a prior declaration

```
function Squared (X : Integer) return Integer;
function Squared (X : Integer) return Integer is
   (X ** 2);
```

Expression Functions Example

Ada 2012

- Expression function

```
function Square (X : Integer) return Integer is (X ** 2);
```

- Is equivalent to

```
function Square (X : Integer) return Integer is
begin
   return X ** 2;
end Square;
```

Quiz

Which statement is True?

A. Expression functions cannot be nested functions.
B. Expression functions require a specification and a body.
C. Expression functions must have at least one "return" statement.
D. Expression functions can have "out" parameters.

Quiz

Which statement is True?

A. Expression functions cannot be nested functions.
B. Expression functions require a specification and a body.
C. Expression functions must have at least one "return" statement.
D. ***Expression functions can have "out" parameters.***

Explanations

A. False, they can be declared just like regular function
B. False, an expression function cannot have a body
C. False, expression functions cannot contain a no `return`
D. Correct, but it can assign to `out` parameters only by calling another function.

Potential Pitfalls

Examples

```
with Ada.Text_IO; use Ada.Text_IO;
procedure Potential_Pitfalls is
   Global_I : Integer  := 0;
   Global_P : Positive := 1;
   Global_S : String   := "Hello";

   procedure Unassigned_Out (A : in Integer; B : out Positive) is
   begin
      if A > 0 then
         B := A;
      end if;
   end Unassigned_Out;

   function Cause_Side_Effect return Integer is
   begin
      Global_I := Global_I + 1;
      return Global_I;
   end Cause_Side_Effect;

   procedure Order_Dependent_Code (X, Y : Integer) is
   begin
      Put_Line (Integer'Image (X) & " / " & Integer'Image (Y));
   end Order_Dependent_Code;

   procedure Aliasing (Param : in     String;
                       I1    : in out Integer;
                       I2    : in out Integer) is
   begin
      Global_S := "World";
      I1       := I1 * 2;
      I2       := I2 * 3;
      Put_Line ("Aliasing string: " & Param);
   end Aliasing;

begin
   Unassigned_Out (-1, Global_P);
   Put_Line ("Global_P = " & Positive'Image (Global_P));

   Order_Dependent_Code (Global_I, Cause_Side_Effect);

   Global_P := Positive'First;
   -- Aliasing (Global_S, Global_I, Global_I); -- compile error
   Aliasing (Global_S, Global_I, Global_P);
   Put_Line ("Global_S: " & Global_S);
   Put_Line ("Global_P: " & Global_P'Image);
end Potential_Pitfalls;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/070_subprograms.html#potential-pitfalls

Mode **out** Risk for Scalars

- Always assign value to `out` parameters
- Else "By-copy" mechanism will copy something back
  - May be junk
  - `Constraint_Error` or unknown behaviour further down

```
procedure P
   (A, B : in Some_Type; Result : out Scalar_Type) is
begin
   if Some_Condition then
      return;  -- Result not set
   end if;
   ...
   Result := Some_Value;
end P;
```

"Side Effects"

- Any effect upon external objects or external environment
  - Typically alteration of non-local variables or states
  - Can cause hard-to-debug errors
  - Not legal for `function` in SPARK
- Can be there for historical reasons
  - Or some design patterns

```
Global : Integer := 0;

function F (X : Integer) return Integer is
begin
   Global := Global + X;
   return Global;
end P;
```

Order-Dependent Code And Side Effects

```
Global : Integer := 0;

function Inc return Integer is
begin
  Global := Global + 1;
  return Global;
end F;

procedure Assert_Equals (X, Y : in Integer);
...
Assert_Equals (Global, Inc);
```

- Language does **not** specify parameters' order of evaluation
- `Assert_Equals` could get called with
  - X → 0, Y → 1 (if `Global` evaluated first)
  - X → 1, Y → 1 (if `Inc` evaluated first)

Parameter Aliasing

- *Aliasing*: Multiple names for an actual parameter inside a subprogram body
- Possible causes:
  - Global object used is also passed as actual parameter
  - Same actual passed to more than one formal
  - Overlapping `array` slices
  - One actual is a component of another actual
- Can lead to code dependent on parameter-passing mechanism
- Ada detects some cases and raises `Program_Error`

```
procedure Update (Doubled, Tripled : in out Integer);
...
Update (Doubled => A,
        Tripled => A);  -- illegal in Ada 2012
```

Functions' Parameter Modes

Ada 2012

- Can be mode `in out` and `out` too
- **Note:** operator functions can only have mode `in`
  - Including those you overload
  - Keeps readers sane
- Justification for only mode `in` prior to Ada 2012
  - No side effects: should be like mathematical functions
  - But side effects are still possible via globals
  - So worst possible case: side effects are possible and necessarily hidden!

Easy Cases Detected and Not Legal

```
procedure Example ( A : in out Positive ) is
   function Increment (This : Integer) return Integer is
   begin
      A := A + This;
      return A;
   end Increment;
   X : array (1 .. 10) of Integer;
begin
   -- order of evaluating A not specified
   X (A) := Increment (A);
end Example;
```

Extended Examples

Tic-Tac-Toe Winners Example (Spec)

```
package TicTacToe is
   type Players is (Nobody, X, O);
   type Move is range 1 .. 9;
   type Game is array (Move) of
     Players;
   function Winner (This : Game)
     return Players;
   ...
end TicTacToe;
```

1 N	2 N	3 N
4 N	5 N	6 N
7 N	8 N	9 N

Tic-Tac-Toe Winners Example (Body)

```
function Winner (This : Game) return Players is
  type Winning_Combinations is range 1 .. 8;
  type Required_Positions   is range 1 .. 3;
  Winning : constant array
    (Winning_Combinations, Required_Positions)
      of Move := (-- rows
                  (1, 2, 3), (4, 5, 6), (7, 8, 9),
                  -- columns
                  (1, 4, 7), (2, 5, 8), (3, 6, 9),
                  -- diagonals
                  (1, 5, 9), (3, 5, 7));

begin
  for K in Winning_Combinations loop
    if This (Winning (K, 1)) /= Nobody and then
      (This (Winning (K, 1)) = This (Winning (K, 2)) and
       This (Winning (K, 2)) = This (Winning (K, 3)))
    then
      return This (Winning (K, 1));
    end if;
  end loop;
  return Nobody;
end Winner;
```

Set Example

```
-- some colors
type Color is (Red, Orange, Yellow, Green, Blue, Violet);
-- truth table for each color
type Set is array (Color) of Boolean;
-- unconstrained array of colors
type Set_Literal is array (Positive range <>) of Color;

-- Take an array of colors and set table value to True
-- for each color in the array
function Make (Values : Set_Literal) return Set;
-- Take a color and return table with color value set to true
function Make (Base : Color) return Set;
-- Return True if the color has the truth value set
function Is_Member (C : Color; Of_Set: Set) return Boolean;

Null_Set : constant Set := (Set'Range => False);
RGB      : Set := Make (
           Set_Literal'( Red, Blue, Green));
Domain   : Set := Make (Green);

if Is_Member (Red, Of_Set => RGB) then ...

-- Type supports operations via Boolean operations,
-- as Set is a one-dimensional array of Boolean
S1, S2 : Set := Make (....);
Union : Set := S1 or S2;
Intersection : Set := S1 and S2;
Difference : Set := S1 xor S2;
```

Set Example (Implementation)

```
function Make (Base : Color) return Set is
  Result : Set := Null_Set;
begin
   Result (Base) := True;
   return Result;
end Make;

function Make (Values : Set_Literal) return Set is
  Result : Set := Null_Set;
begin
  for K in Values'Range loop
    Result (Values (K)) := True;
  end loop;
  return Result;
end Make;

function Is_Member ( C: Color;
                     Of_Set: Set)
                     return Boolean is
begin
  return Of_Set(C);
end Is_Member;
```

Lab

Subprograms Lab

- Requirements
  - Allow the user to fill a list with values and then check to see if a value is in the list
  - Create at least two subprograms:
    - Sort a list of items
    - Search a list of items and return TRUE if found
    - You can create additional subprograms if desired
- Hints
  - Subprograms can be nested inside other subprograms
    - Like inside **main**
  - Try a binary search algorithm if you want to use recursion
    - Unconstrained arrays may be needed

Subprograms Lab Solution - Search

```
function Is_Found (List : List_T;
                   Item : Integer)
                   return Boolean is
begin
   if List'Length = 0 then
      return False;
   elsif List'Length = 1 then
      return List (List'First) = Item;
   else
      declare
         Midpoint : constant Integer := (List'First + List'Last) / 2;
      begin
         if List (Midpoint) = Item then
            return True;
         elsif List (Midpoint) > Item then
            return Is_Found (List
                   (List'First .. Midpoint - 1), Item);
         else -- List(Midpoint) < item
            return Is_Found (List
                   (Midpoint + 1 .. List'Last), Item);
         end if;
      end;
   end if;
end Is_Found;
```

Subprograms Lab Solution - Sort

```
procedure Sort (List : in out List_T) is
   Swapped : Boolean;
   procedure Swap (I, J : in Integer) is
      Temp : constant Integer := List (I);
   begin
      List (I) := List (J);
      List (J) := Temp;
      Swapped  := True;
   end Swap;
begin
   for I in List'First .. List'Last loop
      Swapped := False;
      for J in 1 .. List'Last - I loop
         if List (J) > List (J + 1)
         then
            Swap (J, J + 1);
         end if;
      end loop;
      if not Swapped then
         return;
      end if;
   end loop;
end Sort;
```

Subprograms Lab Solution - Main

```
   procedure Fill (List : out List_T) is
   begin
      Put_Line ("Enter values for list: ");
      for I in List'First .. List'Last
      loop
         List (I) := Integer'Value (Get_Line);
      end loop;
   end Fill;

   Number : Integer;

begin

   Put ("Enter number of elements in list: ");
   Number := Integer'Value (Get_Line);

   declare
      List : List_T (1 .. Number);
   begin
      Fill (List);
      Sort (List);
      loop
         Put ("Enter number to look for: ");
         Number := Integer'Value (Get_Line);
         exit when Number < 0;
         Put_Line (Boolean'Image (Is_Found (List, Number)));
      end loop;
   end;

end Main;
```

Summary

Summary

- `procedure` is abstraction for actions
- `function` is abstraction for value computations
- A `function` may return values of variable size
- Separate declarations are sometimes necessary
  - Mutual recursion
  - Visibility from packages (i.e., exporting)
- Modes allow spec to define effects on actuals
  - Don't have to see the implementation: abstraction maintained
- Parameter-passing mechanism is based on the type
- Watch those side effects!

Type Derivation

Introduction

Type Derivation

- Type *derivation* allows for reusing code
- Type can be **derived** from a **base type**
- Base type can be substituted by the derived type
- Subprograms defined on the base type are **inherited** on derived type
- This is **not** OOP in Ada
  - Tagged derivation **is** OOP in Ada

Ada Mechanisms for Type Inheritance

- *Primitive* operations on types
  - Standard operations like + and -
  - Any operation that acts on the type
- Type derivation
  - Define types from other types that can add limitations
  - Can add operations to the type
- Tagged derivation
  - **This** is OOP in Ada
  - Seen in other chapter

Primitives

Examples

```
package Primitives_Example is

   type Record_T is record
      Field : Integer;
   end record;
   type Access_To_Record_T is access Record_T;
   type Array_T is array (1 .. 10) of Integer;

   procedure Primitive_Of_Record_T (P : in out Record_T) is null;
   function Primitive_Of_Record_T (P : Integer) return Record_T is
     ((Field => P));
   procedure Primitive_Of_Record_T (I : Integer;
                                    P : access Record_T) is null;
   procedure Not_A_Primitive_Of_Record_T
     (I : Integer; P : Access_To_Record_T) is null;

   procedure Primitive_Of_Record_T_And_Array_T
     (P1 : in out Record_T; P2 : in out Array_T) is null;
end Primitives_Example;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/170_tagged_derivation.html#primitives

Primitive Operations

- A type is characterized by two elements
  - Its data structure
  - The set of operations that applies to it
- The operations are called **primitive operations** in Ada

```
type T is new Integer;
procedure Attrib_Function(Value : T);
```

General Rule For a Primitive

- Primitives are subprograms
- **S** is a primitive of type **T** iff
  - **S** is declared in the scope of **T**
  - **S** "uses" type **T**
    - As a parameter
    - As its return type (for `function`)
  - **S** is above *freeze-point*
- Rule of thumb
  - Primitives must be declared **right after** the type itself
  - In a scope, declare at most a **single** type with primitives

```
package P is
   type T is range 1 .. 10;
   procedure P1 (V : T);
   procedure P2 (V1 : Integer; V2 : T);
   function F return T;
end P;
```

Simple Derivation

Examples

```
package Simple_Derivation is
   type Parent_T is range 1 .. 10;
   function Primitive1 (V : Parent_T) return String is
     ("Primitive1 of Parent_T" & V'Image);
   function Primitive2 (V : Parent_T) return String is
     ("Primitive2 of Parent_T" & V'Image);
   function Primitive3 (V : Parent_T) return String is
     ("Primitive3 of Parent_T" & V'Image);

   type Child_T is new Parent_T; -- implicitly gets access to Primitive1

   -- new behavior for Primitive2
   overriding function Primitive2 (V : Child_T) return String is
     ("Primitive2 of Child_T" & V'Image);

   -- remove behavior for Primitive3 from Child_T
   overriding function Primitive3 (V : Child_T) return String is abstract;

   -- add primitive only for Child_T
   not overriding function Primitive4 (V : Child_T) return String is
     ("Primitive4 of Child_T" & V'Image);
end Simple_Derivation;

with Ada.Text_IO;       use Ada.Text_IO;
with Simple_Derivation; use Simple_Derivation;
procedure Test_Simple_Derivation is
   function Not_A_Primitive (V : Parent_T) return String is
     ("Not_A_Primitive" & V'Image);
   Parent_V : Parent_T := 1;
   Child_V  : Child_T  := 2;
begin
   Put_Line ("Parent_V - " & Primitive1 (Parent_V));
   Put_Line ("Parent_V - " & Primitive2 (Parent_V));
   Put_Line ("Parent_V - " & Primitive3 (Parent_V));
   -- Put_Line ("Parent_V - " & Primitive4 (Parent_V)); -- illegal

   Put_Line ("Child_V - " & Primitive1 (Child_V));
   Put_Line ("Child_V - " & Primitive2 (Child_V));
   -- Put_Line ("Child_V - " & Primitive3 (Child_V)); -- illegal
   Put_Line ("Child_V - " & Primitive4 (Child_V));

   Put_Line (Not_A_Primitive (Parent_V));
   Put_Line (Not_A_Primitive (Parent_T (Child_V)));
end Test_Simple_Derivation;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/170_tagged_derivation.html#simple-derivation

Simple Type Derivation

- Any type (except `tagged`) can be derived

```
type Child is new Parent;
```

- Child inherits from:
  - The data **representation** of the parent
  - The **primitives** of the parent
- Conversions are possible from child to parent

```
type Parent is range 1 .. 10;
procedure Prim (V : Parent);
type Child is new Parent;  -- Freeze Parent
procedure Not_A_Primitive (V : Parent);
C : Child;
...
Prim (C);  -- Implicitly declared
Not_A_Primitive (Parent (C));
```

Simple Derivation and Type Structure

- The type "structure" can not change
  - `array` cannot become `record`
  - Integers cannot become floats
- But can be **constrained** further
- Scalar ranges can be reduced

```
type Tiny_Int is range -100 .. 100;
type Tiny_Positive is new Tiny_Int range 1 .. 100;
```

- Unconstrained types can be constrained

```
type Arr is array (Integer range <>) of Integer;
type Ten_Elem_Arr is new Arr (1 .. 10);
type Rec (Size : Integer) is record
   Elem : Arr (1 .. Size);
end record;
type Ten_Elem_Rec is new Rec (10);
```

Overriding Indications

Ada 2005

- **Optional** indications
- Checked by compiler

```
type Root is range 1 .. 100;
procedure Prim (V : Root);
type Child is new Root;
```

- **Replacing** a primitive: `overriding` indication

```
overriding procedure Prim (V : Child);
```

- **Adding** a primitive: `not overriding` indication

```
not overriding procedure Prim2 (V : Child);
```

- **Removing** a primitive: `overriding` as `abstract`

```
overriding procedure Prim (V : Child) is abstract;
```

Quiz

```
type T1 is range 1 .. 100;
procedure Proc_A (X : in out T1);

type T2 is new T1 range 2 .. 99;
procedure Proc_B (X : in out T1);
procedure Proc_B (X : in out T2);

-- Other scope
procedure Proc_C (X : in out T2);

type T3 is new T2 range 3 .. 98;

procedure Proc_C (X : in out T3);
```

Which are `T1`'s primitives

A. `Proc_A`
B. `Proc_B`
C. `Proc_C`
D. No primitives of `T1`

.

Quiz

```
type T1 is range 1 .. 100;
procedure Proc_A (X : in out T1);

type T2 is new T1 range 2 .. 99;
procedure Proc_B (X : in out T1);
procedure Proc_B (X : in out T2);

-- Other scope
procedure Proc_C (X : in out T2);

type T3 is new T2 range 3 .. 98;

procedure Proc_C (X : in out T3);
```

Which are `T1`'s primitives

A. ***`Proc_A`***
B. `Proc_B`
C. `Proc_C`
D. No primitives of `T1`

Explanations

A. Correct
B. Freeze: `T1` has been derived
C. Freeze: scope change
D. Incorrect

.

Summary

Summary

- *Primitive* of a type
  - Subprogram above **freeze-point** that takes or return the type
  - Can be a primitive for **multiple types**
- Freeze point rules can be tricky
- Simple type derivation
  - Types derived from other types can only **add limitations**
    - Constraints, ranges
    - Cannot change underlying structure

Overloading

Introduction

Introduction

- *Overloading* is the use of an already existing name to define a **new** entity
- Historically, only done as part of the language **implementation**
  - Eg. on operators
  - Float vs integer vs pointers arithmetic
- Several languages allow **user-defined** overloading
  - C++
  - Python (limited to operators)
  - Haskell

Visibility and Scope

- Overloading is **not** re-declaration
- Both entities **share** the name
  - No hiding
  - Compiler performs **name resolution**
- Allowed to be declared in the **same scope**
  - Remember this is forbidden for "usual" declarations

Overloadable Entities In Ada

- Identifiers for subprograms
  - Both procedure and function names
- Identifiers for enumeration values (enumerals)
- Language-defined operators for functions

```
procedure Put (Str : in String);
procedure Put (C : in Complex);
function Max (Left, Right : Integer) return Integer;
function Max (Left, Right : Float)   return Float;
function "+" (Left, Right : Rational) return Rational;
function "+" (Left, Right : Complex)  return Complex;
function "*" (Left : Natural; Right : Character)
      return String;
```

Function Operator Overloading Example

```
--  User-defined overloading
function "+" (L,R : Complex) return Complex is
begin
   return (L.Real_Part + R.Real_Part,
           L.Imaginary + R.Imaginary);
end "+";

A, B, C : Complex;
I, J, K : Integer;

I := J + K; -- overloaded operator (predefined)
A := B + C; -- overloaded operator (user-defined)
```

Benefits and Risk of Overloading

- Management of the name space
  - Support for abstraction
  - Linker will not simply take the first match and apply it globally
- Safe: compiler will reject ambiguous calls
- Sensible names are the programmer's job

```
function "+" ( L, R : Integer ) return String is
begin
   return Integer'Image ( L - R );
end "+";
```

Enumerals and Operators

Examples

```
with Ada.Text_IO; use Ada.Text_IO;
procedure Enumerals_And_Operators is
   type Colors_T is (Blue, Yellow, Black, Green, Red);
   type Rgb_T is (Red, Green, Blue);
   type Stoplight_T is (Green, Yellow, Red);

   Color : constant Colors_T    := Red;
   Rgb   : constant Rgb_T       := Red;
   Light : constant Stoplight_T := Red;

   type Miles_T is digits 6;
   type Hour_T is digits 6;
   type Speed_T is digits 6;
   function "/" (M : Miles_T; H : Hour_T) return Speed_T is
      (Speed_T (Float (M) / Float (H)));
   function "*" (Mph : Speed_T; H   : Hour_T) return Miles_T is
      (Miles_T (Float (Mph) * Float (H)));

   M   : Miles_T         := Miles_T (Col);
   H   : constant Hour_T := Hour_T (Line);
   Mph : Speed_T;

begin
   Put_Line (Color'Image & " " & Rgb'Image & " " & Light'Image);
   Mph := M / H;
   M   := Mph * H;
   Put_Line (Mph'Image & M'Image);

   Mph := "/" (M => M, H => H);
   M := "*" (Mph, H);
   Put_Line (Mph'Image & M'Image);
end Enumerals_And_Operators;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/090_overloading.html#enumerals-and-operators

Overloading Enumerals

- Each is treated as if a function name (identifier)
- Thus same rules as for function identifier overloading

```
type Stop_Light is (Red, Yellow, Green);
type Colors is (Red, Blue, Green);
Shade : Colors := Red;
Current_Value : Stop_Light := Red;
```

Overloadable Operator Symbols

- Only those defined by the language already
  - Users cannot introduce new operator symbols
- Note that assignment (:=) is not an operator
- Operators (in precedence order)

Logicals	and, or, xor
Relationals	<, <=, =, >=, >
Unary	+, -
Binary	+, -, &
Multiplying	*, /, `mod`, `rem`
Highest precedence	**, `abs`, `not`

Parameters for Overloaded Operators

- Must not change syntax of calls
  - Number of parameters must remain same (unary, binary...)
  - No default expressions allowed for operators
- Infix calls use positional parameter associations
  - Left actual goes to first formal, right actual goes to second formal
  - Definition

```
function "*" (Left, Right : Integer) return Integer;
```

  - Usage

```
X := 2 * 3;
```

- Named parameter associations allowed but ugly
  - Requires prefix notion for call

```
X := "*" ( Left => 2, Right => 3 );
```

Call Resolution

Examples

```
with Ada.Text_IO; use Ada.Text_IO;
procedure Call_Resolution is
   type Colors_T is (Red, Orange, Yellow, Green, Blue, Indigo, Violet);
   type Rgb_T is (Red, Green, Blue);
   function Str (P : Colors_T) return String is (Colors_T'Image (P));
   function Str (P : Rgb_T) return String is (Rgb_T'Image (P));
   procedure Print (Color : Colors_T) is
   begin
      Put_Line (Str (Color));
   end Print;
   procedure Print (Rgb : Rgb_T) is
   begin
      Put_Line (Str (Rgb));
   end Print;
   procedure Print (P1 : Colors_T; P2 : Rgb_T) is null;

begin
   Put_Line (Str (Yellow));
   -- Put_Line (Str (Red)); -- compile error
   Print (Orange);
   Print (Rgb => Red);
   Print (Color => Blue);
   Print (Red, Red);
end Call_Resolution;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/090_overloading.html#call-resolution

Call Resolution

- Compilers must reject ambiguous calls
- *Resolution* is based on the calling context
  - Compiler attempts to find a matching **profile**
  - Based on **Parameter** and **Result** Type
- Overloading is not re-definition, or hiding
  - More than one matching profile is ambiguous

```
type Complex is ...
function "+" (L, R : Complex) return Complex;
A, B : Complex := some_value;
C : Complex := A + B;
D : Real := A + B;  -- illegal!
E : Real := 1.0 + 2.0;
```

Profile Components Used

- Significant components appear in the call itself
  - **Number** of parameters
  - **Order** of parameters
  - **Base type** of parameters
  - **Result** type (for functions)
- Insignificant components might not appear at call
  - Formal parameter **names** are optional
  - Formal parameter **modes** never appear
  - Formal parameter **subtypes** never appear
  - **Default** expressions never appear

```
Display (X);
Display (Foo => X);
Display (Foo => X, Bar => Y);
```

Manually Disambiguating Calls

- Qualification can be used
- Named parameter association can be used
  - Unless name is ambiguous

```
type Stop_Light is (Red, Yellow, Green);
type Colors is (Red, Blue, Green);
procedure Put (Light : in Stop_Light);
procedure Put (Shade : in Colors);

Put (Red);   -- ambiguous call
Put (Yellow);   -- not ambiguous: only 1 Yellow
Put (Colors'(Red)); -- using type to distinguish
Put (Light => Green); -- using profile to distinguish
```

Overloading Example

```
function "+" (Left : Position; Right : Offset)
  return Position is
begin
   return Position'( Left.Row + Right.Row, Left.Column + Right.Col);
end "+";

function Acceptable (P : Position) return Boolean;
type Positions is array (Moves range <>) of Position;

function Next (Current : Position) return Positions is
  Result : Positions (Moves range 1 .. 4);
  Count  : Moves := 0;
  Test   : Position;
begin
  for K in Offsets'Range loop
    Test := Current + Offsets(K);
    if Acceptable (Test) then
      Count := Count + 1;
      Result (Count) := Test;
    end if;
  end loop;
  return Result (1 .. Count);
end Next;
```

Quiz

```
type Vertical_T is (Top, Middle, Bottom);
type Horizontal_T is (Left, Middle, Right);
function "*" (H : Horizontal_T; V : Vertical_T) return Positive;
function "*" (V : Vertical_T; H : Horizontal_T) return Positive;
P : Positive;
```

Which statement is not legal?

A. `P := Horizontal_T'(Middle) * Middle;`
B. `P := Top * Right;`
C. `P := "*" (Middle, Top);`
D. `P := "*" (H => Middle, V => Top);`

Quiz

```
type Vertical_T is (Top, Middle, Bottom);
type Horizontal_T is (Left, Middle, Right);
function "*" (H : Horizontal_T; V : Vertical_T) return Positive;
function "*" (V : Vertical_T; H : Horizontal_T) return Positive;
P : Positive;
```

Which statement is not legal?

A. `P := Horizontal_T'(Middle) * Middle;`
B. `P := Top * Right;`
C. `P := "*" (Middle, Top);`
D. *`P := "*" (H => Middle, V => Top);`*

Explanations

A. Qualifying one parameter resolves ambiguity
B. No overloaded names
C. Use of Top resolves ambiguity
D. When overloading subprogram names, best to not just switch the order of parameters

User-Defined Equality

Examples

```
with Ada.Text_IO; use Ada.Text_IO;
procedure User_Defined_Equality is
   type Array_T is array (1 .. 10) of Integer;
   type List_T is record
      List  : Array_T;
      Count : Integer := 0;
   end record;

   function "=" (L, R : List_T) return Boolean is
   begin
      if L.Count /= R.Count then
         Put_Line ("Count is off");
         return False;
      else
         for I in 1 .. L.Count loop
            if L.List (I) /= R.List (I) then
               Put_Line ("elements don't match");
               return False;
            end if;
         end loop;
      end if;
      return True;
   end "=";
   L, R : List_T := (List => (others => 1), Count => 3);
begin
   Put_Line (Boolean'Image (L = R));
   L.List (2) := 0;
   Put_Line (Boolean'Image (L = R));
   R.Count := 1;
   Put_Line (Boolean'Image (L = R));
end User_Defined_Equality;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/090_overloading.html#user-defined-equality

User-Defined Equality

- Allowed like any other operator
  - Must remain a binary operator
- Typically declared as `return Boolean`
- Hard to do correctly for composed types
  - Especially **user-defined** types
  - Issue of *Composition of equality*

Lab

Overloading Lab

- Requirements
  - Create multiple functions named "Convert" to convert between digits and text representation
    - One routine should take a digit and return the text version (e.g. **3** would return **three**)
    - One routine should take text and return the digit (e.g. **two** would return **2**)
  - Query the user to enter text or a digit and print it's equivalent
  - If the user enters consecutive entries that are equivalent, print a message
    - e.g. **4** followed by **four** should get the message
- Hints
  - You can use enumerals for the text representation
    - Then use *'image* / *'value* where needed
  - Use an equivalence function two compare different types

Overloading Lab Solution - Conversion Functions

```
type Digit_T is range 0 .. 9;
type Digit_Name_T is
  (Zero, One, Two, Three, Four, Five, Six, Seven, Eight, Nine);

function Convert (Value : Digit_T) return Digit_Name_T;
function Convert (Value : Digit_Name_T) return Digit_T;
function Convert (Value : Character) return Digit_Name_T;
function Convert (Value : String) return Digit_T;

function "=" (L : Digit_Name_T; R : Digit_T) return Boolean is (Convert (L) = R);

function Convert (Value : Digit_T) return Digit_Name_T is
  (case Value is when 0 => Zero,  when 1 => One,
                 when 2 => Two,   when 3 => Three,
                 when 4 => Four,  when 5 => Five,
                 when 6 => Six,   when 7 => Seven,
                 when 8 => Eight, when 9 => Nine);

function Convert (Value : Digit_Name_T) return Digit_T is
  (case Value is when Zero  => 0, when One => 1,
                 when Two   => 2, when Three => 3,
                 when Four  => 4, when Five => 5,
                 when Six   => 6, when Seven => 7,
                 when Eight => 8, when Nine => 9);

function Convert (Value : Character) return Digit_Name_T is
  (case Value is when '0' => Zero,  when '1' => One,
                 when '2' => Two,   when '3' => Three,
                 when '4' => Four,  when '5' => Five,
                 when '6' => Six,   when '7' => Seven,
                 when '8' => Eight, when '9' => Nine,
                 when others => Zero);

function Convert (Value : String) return Digit_T is
  (Convert (Digit_Name_T'Value (Value)));
```

Overloading Lab Solution - Main

```
   Last_Entry : Digit_T := 0;

begin
   loop
      Put ("Input: ");
      declare
         Str : constant String := Get_Line;
      begin
         exit when Str'Length = 0;
         if Str (Str'First) in '0' .. '9' then
            declare
               Converted : constant Digit_Name_T := Convert (Str (Str'First));
            begin
               Put (Digit_Name_T'Image (Converted));
               if Converted = Last_Entry then
                  Put_Line (" - same as previous");
               else
                  Last_Entry := Convert (Converted);
                  New_Line;
               end if;
            end;
         else
            declare
               Converted : constant Digit_T := Convert (Str);
            begin
               Put (Digit_T'Image (Converted));
               if Converted = Last_Entry then
                  Put_Line (" - same as previous");
               else
                  Last_Entry := Converted;
                  New_Line;
               end if;
            end;
         end if;
      end;
   end loop;
end Main;
```

Summary

Summary

- Ada allows user-defined overloading
  - Identifiers and operator symbols
- Benefits easily outweigh danger of senseless names
  - Can have nonsensical names without overloading
- Compiler rejects ambiguous calls
- Resolution is based on the calling context
  - *Parameter and Result Type Profile*
- Calling context is those items present at point of call
  - Thus modes etc. don't affect overload resolution
- User-defined equality is allowed
  - But is tricky

Library Units

Introduction

Modularity

- Ability to split large system into subsystems
- Each subsystem can have its own components
- And so on ...

Library Units

Examples

```
package Named_Common is
   X : Integer; -- valid object for life of application
   Y : Float;    -- valid object for life of application
end Named_Common;

procedure Library_Procedure (Parameter : in out Integer);

with Ada.Text_IO; use Ada.Text_IO;
procedure Library_Procedure (Parameter : in out Integer) is
   -- X is visible to Library_Procedure and Nested_Procedure
   X : constant Integer := Parameter;
   procedure Nested_Procedure is
      -- Y is only visible to Nested_Procedure
      Y : constant Integer := X * 2;
   begin
      Parameter := X * Y;
   end Nested_Procedure;
begin
   Nested_Procedure;
   Put_Line ("parameter = " & Parameter'Image);
end Library_Procedure;

with Library_Procedure;
with Named_Common;
procedure Main is
begin
   Named_Common.X := 123;
   Library_Procedure (Named_Common.X);
end Main;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/095_library_units.html#library-units

Library Units

- Those not nested within another program unit
- Candidates
  - Subprograms
  - Packages
  - Generic Units
  - Generic Instantiations
  - Renamings
- Restrictions
  - No library level tasks
    - They are always nested within another unit
  - No overloading at library level
  - No library level functions named as operators

Library Units

```
package Operating_System is
   procedure Foo( ... );
   procedure Bar( ... );
   package Process_Manipulation is
      ...
   end Process_Manipulation;
   package File_System is
      ...
   end File_System;
end Operating_System;
```

- **Operating_System** is library unit
- **Foo**, **Bar**, etc - not library units

No 'Object' Library Items

```
package Library_Package is
   ...
end Library_Package;

-- Illegal: no such thing as "file scope"
Library_Object : Integer;

procedure Library_Procedure;

function Library_Function (Formal : in out Integer) is
  Local : Integer;
begin
   ...
end Library_Function;
```

Declared Object "Lifetimes"

- Same as their enclosing declarative region
  - Objects are always declared within some declarative region
- No `static` etc. directives as in C
- Objects declared within any subprogram
  - Exist only while subprogram executes

```
procedure Library_Subprogram is
   X : Integer;
   Y : Float;
begin
   ...
end Library_Subprogram;
```

Objects In Library Packages

- Exist as long as program executes (i.e., "forever")

```
package Named_Common is
   X : Integer; -- valid object for life of application
   Y : Float;   -- valid object for life of application
end Named_Common;
```

Objects In Non-library Packages

- Exist as long as region enclosing the package

```
procedure P is
   X : Integer; -- available while in P and Inner
   package Inner is
      Z : Boolean; -- available while in Inner
   end Inner;
   Y : Real; -- available while in P
begin
   ...
end P;
```

Program "Lifetime"

- Run-time library is initialized
- All (any) library packages are elaborated
  - Declarations in package declarative part are elaborated
  - Declarations in package body declarative part are elaborated
  - Executable part of package body is executed (if present)
- Main program's declarative part is elaborated
- Main program's sequence of statements executes
- Program executes until all threads terminate
- All objects in library packages cease to exist
- Run-time library shuts down

Library Unit Subprograms

- Recall: separate declarations are optional
  - Body can act as declaration if no declaration provided
- Separate declaration provides usual benefits
  - Changes/recompilation to body only require relinking clients
- File 1 (p.ads for GNAT)

```
procedure P (F : in Integer);
```

- File 2 (p.adb for GNAT)

```
procedure P (F : in Integer) is
begin
   ...
end P;
```

Library Unit Subprograms

- Specifications in declaration and body must conform
  - Example
    - Spec for P

```
procedure P (F : in integer);
```

    - Body for P

```
procedure P (F : in float) is
begin
...
end P;
```

  - Declaration creates subprogram **P** in library
  - Declaration exists so body does not act as declaration
  - Compilation of file "p.adb" must fail
- New declaration with same name replaces old one
- Thus cannot overload library units

Main Subprograms

- Must be library subprograms
- No special program unit name required
- Can be many per program library
- Always can be procedures
- Can be functions if implementation allows it
  - Execution environment must know how to handle result

```
with Ada.Text_IO;
procedure Hello is
begin
   Ada.Text_IO.Put( "Hello World" );
end Hello;
```

Dependencies

Examples

```
with Ada.Text_IO;
package Base_Types is
   type Position_T is record
      Line   : Ada.Text_IO.Positive_Count;
      Column : Ada.Text_IO.Positive_Count;
   end record;
end Base_Types;

-- no need to "with" ada.text_io
with Base_Types;
package Files is
   subtype Name_T is String (1 .. 12);
   type File_T is record
      Name     : Name_T                := (others => ' ');
      Position : Base_Types.Position_T := (Line => 1, Column => 1);
   end record;
   function Create (Name : Name_T) return File_T;
end Files;

package body Files is
   -- "with" of base_types inherited from spec
   Default_Position : constant Base_Types.Position_T := (1, 1);
   function Create (Name : Name_T) return File_T is
     (Name => Name, Position => Default_Position);
end Files;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/095_library_units.html#with-clauses

with Clauses

- Specify the library units that a compilation unit depends upon
  - The "context" in which the unit is compiled
- Syntax (simplified)

```
context_clause ::= { context_item }
context_item ::= with_clause | use_clause
with_clause ::= with library_unit_name
                  { , library_unit_name };
```

```
with Ada.Text_IO; -- dependency
procedure Hello is
begin
  Ada.Text_IO.Put ("Hello World");
end Hello;
```

with Clauses Syntax

- Helps explain restrictions on library units
  - No overloaded library units
  - If overloading allowed, which **P** would `with P;` refer to?
  - No library unit functions names as operators
    - Mostly because of no overloading

What To Import

- Need only name direct dependencies
  - Those actually referenced in the corresponding unit
- Will not cause compilation of referenced units
  - Unlike "include directives" of some languages

```
package A is
  type Something is ...
end A;

with A;
package B is
  type Something is record
    Field : A.Something;
  end record;
end B;

with B; -- no "with" of A
procedure Foo is
  X : B.Something;
begin
  X.Field := ...
```

Summary

Summary

- Library Units are "standalone" entities
  - Can contain subunits with similar structure
- `with` clauses interconnect library units
  - Express dependencies of the one being compiled
  - Not textual inclusion!

Packages

Introduction

Packages

- Enforce separation of client from implementation
  - In terms of compile-time visibility
  - For data
  - For type representation, when combined with `private` types
    - Abstract Data Types
- Provide basic namespace control
- Directly support software engineering principles
  - Especially in combination with `private` types
  - Modularity
  - Information Hiding (Encapsulation)
  - Abstraction
  - Separation of Concerns

Separating Interface and Implementation

- *Implementation* and *specification* are textually distinct from each other
  - Typically in separate files
- Clients can compile their code before body exists
  - All they need is the package specification
  - Full client/interface consistency is guaranteed

```
package Float_Stack is
   Max : constant := 100;
   procedure Push (X : in Float);
   procedure Pop (X : out Float);
end Float_Stack;
```

Uncontrolled Visibility Problem

- Clients have too much access to representation
  - Data
  - Type representation
- Changes force clients to recode and retest
- Manual enforcement is not sufficient
- Why fixing bugs introduces new bugs!

Basic Syntax and Nomenclature

```
package_declaration ::= package_specification;
```

- Spec

```
package_specification ::=
   package name is
      {basic_declarative_item}
   end [name];
```

- Body

```
package_body ::=
   package body name is
      declarative_part
   end [name];
```

Declarations

Examples

```
package Global_Data is
   Object : Integer := 100;
   type Float_T is digits 6;
end Global_Data;

with Global_Data;
package Float_Stack is
   Max : constant Integer := Global_Data.Object;
   procedure Push (X : in Global_Data.Float_T);
   function Pop return Global_Data.Float_T;
end Float_Stack;

package body Float_Stack is
   Local_Object : Global_Data.Float_T;
   procedure Not_Exported is null;
   procedure Push (X : in Global_Data.Float_T) is
   begin
      Not_Exported;
      Local_Object := X;
   end Push;
   function Pop return Global_Data.Float_T is (Local_Object);
end Float_Stack;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/100_packages.html#declarations

Package Declarations

- Required in all cases
  - Cannot have a package without the declaration
- Describe the client's interface
  - Declarations are exported to clients
  - Effectively the "pin-outs" for the black-box
- When changed, requires clients recompilation
  - The "pin-outs" have changed

```
package Float_Stack is
  Max : constant := 100;
  procedure Push (X : in Float);
  procedure Pop (X : out Float);
end Float_Stack;

package Data is
   Object : integer;
end Data;
```

Compile-Time Visibility Control

- Items in the declaration are visible to users

```
package name  is
   -- exported declarations of
   --   types, variables, subprograms ...
end name;
```

- Items in the body are never externally visible
  - Compiler prevents external references

```
package body name  is
   -- hidden declarations of
   --   types, variables, subprograms ...
   -- implementations of exported subprograms etc.
end name;
```

Example of Exporting To Clients

- Variables, types, exception, subprograms, etc.
  - The primary reason for separate subprogram declarations

```
package P is
   procedure This_Is_Exported;
end P;

package body P is
   procedure Not_Exported is
      ...
   procedure This_Is_Exported is
      ...
end P;
```

Referencing Exported Items

- Achieved via "dot notation"
- Package Specification

```
package Float_Stack is
   Max : constant := 100;
   procedure Push (X : in Float);
   procedure Pop (X : out Float);
end Float_Stack;
```

- Package Reference

```
with Float_Stack;
procedure Test is
    X : Float;
begin
    Float_Stack.Pop (X);
    Float_Stack.Push (12.0);
    if Count < Float_Stack.Max then ...
```

Bodies

Examples

```
package Body_Not_Allowed is
   type Real is digits 12;
   type Device_Coordinates is record
      X, Y : Integer;
   end record;
   type Normalized_Coordinates is record
      X, Y : Real range 0.0 .. 1.0;
   end record;
   -- nothing to implement, so no body allowed
end Body_Not_Allowed;

package Body_Required is
   subtype Rows is Integer range 1 .. 24;
   subtype Columns is Integer range 1 .. 80;
   type Position is record
      Row : Rows    := Rows'First;
      Col : Columns := Columns'First;
   end record;
   -- The following need to be defined in the body
   procedure Move_Cursor (To : in Position);
   procedure Home;
end Body_Required;

with Ada.Text_IO; use Ada.Text_IO;
package body Body_Required is
   -- This function is not visible outside this package
   function Unsigned (Input : Integer) return String is
      Str : constant String := Integer'Image (Input);
   begin
      return Str (2 .. Str'Length);
   end Unsigned;
   procedure Move_Cursor (To : in Position) is
   begin
      Put (ASCII.ESC & "I" & Unsigned(To.Row) & ";" & Unsigned(To.Col) & "H");
   end Move_Cursor;
   procedure Home is null; -- not yet implemented
end Body_Required;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/100_packages.html#bodies

Package Bodies

- Dependent on corresponding package specification
  - Obsolete if specification changed
- Clients need only to relink if body changed
  - Any code that would require editing would not have compiled in the first place
- Necessary for specifications that require a completion, for example:
  - Subprogram bodies
  - Task bodies
  - Incomplete types in `private` part
  - Others...

Bodies Are Never Optional

- Either required for a given spec or not allowed at all
  - Based on declarations in that spec
- A change from Ada 83
- A (nasty) justification example will be shown later

Example Spec That Cannot Have A Body

```
package Graphics_Primitives is
   type Real is digits 12;
   type Device_Coordinates is record
      X, Y : Integer;
   end record;
   type Normalized_Coordinates is record
      X, Y : Real range 0.0 .. 1.0;
   end record;
   type Offset is record
      X, Y : Real range -1.0 .. 1.0;
   end record;
   -- nothing to implement, so no body allowed
end Graphics_Primitives;
```

Example Spec Requiring A Package Body

```
package VT100 is
   subtype Rows is Integer range 1 .. 24;
   subtype Columns is Integer range 1 .. 80;
   type Position is record
      Row  : Rows := Rows'First;
      Col : Columns := Columns'First;
   end record;
    -- The following need to be defined in the body
   procedure Move_Cursor (To : in Position);
   procedure Home;
   procedure Clear_Screen;
   procedure Cursor_Up (Count : in Positive := 1);
end VT100;
```

Required Body Example

```
package body VT100 is
   -- This function is not visible outside this package
   function Unsigned (Input : Integer) return String is
      Str : constant String := Integer'Image (Input);
   begin
      return Str (2 .. Str'length);
   end Unsigned;
   procedure Move_Cursor (To : in Position) is
   begin
      Text_IO.Put (ASCII.Esc & 'I' &
                   Unsigned(To.Row) & ';' &
                   Unsigned(To.Col) & 'H');
   end Move_Cursor;
   procedure Home is
   begin
      Text_IO.Put (ASCII.Esc & "iH");
   end Home;
   procedure Cursor_Up (Count : in Positive := 1) is ...
      ...
end VT100;
```

Quiz

```
package P is
   Object_One : Integer;
   procedure One (P : out Integer);
end P;
```

Which completion(s) is(are) correct for `package P`?

A. `No completion is needed`

B.
```
package body P is
   procedure One (P : out Integer) is null;
end P;
```

C.
```
package body P is
   Object_One : Integer;
   procedure One (P : out Integer) is
   begin
     P := Object_One;
   end One;
end P;
```

D.
```
package body P is
   procedure One (P : out Integer) is
   begin
     P := Object_One;
   end One;
end P;
```

```
package P is
   Object_One : Integer;
   procedure One ( P : out Integer );
end P;
```

Which is a valid completion of package P?

A. No completion needed

B.
```
package body P is
   procedure One ( P : out Integer ) is null;
end P;
```

C.
```
package body P is
   Object_One : integer;
   procedure One ( P : out Integer ) is
   begin
     P := Object_One;
   end One;
end P;
```

D.
```
package body P is
   procedure One ( P : out Integer ) is
   begin
     P := Object_One;
   end One;
end P;
```

Quiz

```
package P is
   Object_One : Integer;
   procedure One (P : out Integer);
end P;
```

Which completion(s) is(are) correct for `package P`?

A. `No completion is needed`

B.
```
package body P is
   procedure One (P : out Integer) is null;
end P;
```

C.
```
package body P is
   Object_One : Integer;
   procedure One (P : out Integer) is
   begin
     P := Object_One;
   end One;
end P;
```

D.
```
package body P is
   procedure One (P : out Integer) is
   begin
     P := Object_One;
   end One;
end P;
```

A. Procedure One must have a body
B. Parameter P is `out` but not assigned
C. Redeclaration of Object_One

```
package P is
   Object_One : Integer;
   procedure One ( P : out Integer );
end P;
```

Which is a valid completion of package P?

A. No completion needed

B.
```
package body P is
   procedure One ( P : out Integer ) is null;
end P;
```

C.
```
package body P is
   Object_One : integer;
   procedure One ( P : out Integer ) is
   begin
     P := Object_One;
   end One;
end P;
```

D.
```
package body P is
   procedure One ( P : out Integer ) is
   begin
     P := Object_One;
   end One;
end P;
```

Explanations

A. Procedure One must have a body
B. No assignment of a value to `out` parameter
C. Cannot duplicate `Object_One`
D. Correct

Executable Parts

Examples

```
package Executable_Part is
   Visible_Seed : Integer;
   function Number return Float;
end Executable_Part;

with Ada.Text_IO; use Ada.Text_IO;
package body Executable_Part is
   Hidden_Seed : Integer;
   procedure Initialize (Seed1 : out Integer; Seed2 : out Integer) is
   begin
      Seed1 := Integer'First;
      Seed2 := Integer'Last;
   end Initialize;
   function Number return Float is (0.0); -- not yet implemented
begin
   Put_Line ("Elaborating Executable_Part");
   Initialize (Visible_Seed, Hidden_Seed);
end Executable_Part;

package Force_Body is
   pragma Elaborate_Body;
   Global_Data : array (1 .. 10) of Integer;
end Force_Body;

-- without Elaborate_Body, this is illegal
with Ada.Text_IO; use Ada.Text_IO;
package body Force_Body is
begin
   Put_Line ("Elaborating Force_Body");
   for I in Global_Data'Range loop
      Global_Data (I) := I * 100;
   end loop;
end Force_Body;

with Executable_Part;
with Force_Body;
procedure Main is
begin
   null;
end Main;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/100_packages.html#executable-parts

Optional Executable Part

```
package_body ::=
    package body name is
       declarative_part
    [ begin
       handled_sequence_of_statements ]
    end [ name ];
```

Executable Part Semantics

- Executed only once, when package is elaborated
- Ideal when statements are required for initialization
  - Otherwise initial values in variable declarations would suffice

```
package body Random is
   Seed1, Seed2 : Integer;
   Call_Count : Natural := 0;
   procedure Initialize (Seed1 : out Integer;
                         Seed2 : out Integer) is ...
   function Number return Real is ...
begin -- Random
   Initialize (Seed1, Seed2);
end Random;
```

Requiring/Rejecting Bodies Justification

- Consider the alternative: an optional package body that becomes obsolete prior to building
- Builder could silently choose not to include the package in executable
  - Package executable part might do critical initialization!

```
package P is
   Data : array (L .. U) of
          Integer;
end P;

package body P is
   ...
begin
   for K in Data'Range loop
      Data(K) := ...
   end loop;
end P;
```

Forcing A Package Body To be Required

- Use
  `pragma Elaborate_Body`
  - Says to elaborate body immediately after spec
  - Hence there must be a body!
- Additional pragmas we will examine later

```
package P is
   pragma Elaborate_Body;
   Data : array (L .. U) of
          Integer;
end P;

package body P is
   ...
begin
   for K in Data'Range loop
      Data(K) := ...
   end loop;
end P;
```

Idioms

Examples

```
package Constants is
   Polar_Radius      : constant := 20_856_010.51;
   Equatorial_Radius : constant := 20_926_469.20;
   Earth_Diameter    : constant :=
     2.0 * ((Polar_Radius + Equatorial_Radius) / 2.0);
end Constants;

package Global_Data is
   Longitudinal_Velocity     : Float := 0.0;
   Longitudinal_Acceleration : Float := 0.0;
   Lateral_Velocity          : Float := 0.0;
   Lateral_Acceleration      : Float := 0.0;
   Vertical_Velocity         : Float := 0.0;
   Vertical_Acceleration     : Float := 0.0;
end Global_Data;

package Related_Units is
   type Vector is array (Positive range <>) of Float;
   function "+" (L, R : Vector) return Vector;
   function "-" (L, R : Vector) return Vector;
end Related_Units;

package body Related_Units is
   -- nothing is implemented yet!
   function "+" (L, R : Vector) return Vector is (L);
   function "-" (L, R : Vector) return Vector is (L);
end Related_Units;

package Stack_Abstract_Data_Machine is
   procedure Push (X : in Float);
   procedure Pop (X : out Float);
   function Empty return Boolean;
   function Full return Boolean;
end Stack_Abstract_Data_Machine;

package body Stack_Abstract_Data_Machine is
   -- nothing is implemented yet!
   procedure Push (X : in Float) is null;
   procedure Pop (X : out Float) is null;
   function Empty return Boolean is (True);
   function Full return Boolean is (True);
end Stack_Abstract_Data_Machine;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/100_packages.html#idioms

Named Collection of Declarations

- Exports:
  - Objects (constants and variables)
  - Types
  - Exceptions
- Does not export operations

```
package Physical_Constants is
   Polar_Radius_in_feet    : constant := 20_856_010.51;
   Equatorial_Radius_in_feet : constant := 20_926_469.20;
   Earth_Diameter_in_feet : constant := 2.0 *
         ((Polar_Radius_in_feet + Equatorial_Radius_in_feet)/2.0)
   Sea_Level_Air_Density : constant := 0.002378; --slugs/foot**3
   Altitude_Of_Tropopause_in_feet : constant := 36089.0;
   Tropopause_Temperature_in_celsius : constant := -56.5;
end Physical_Constants;
```

Named Collection of Declarations (2)

- Effectively application global data

```
package Equations_of_Motion is
   Longitudinal_Velocity : Real := 0.0;
   Longitudinal_Acceleration : Real := 0.0;
   Lateral_Velocity  : Real := 0.0;
   Lateral_Acceleration : Real := 0.0;
   Vertical_Velocity : Real:= 0.0;
   Vertical_Acceleration : Real:= 0.0;
   Pitch_Attitude : Real:= 0.0;
   Pitch_Rate : Real:= 0.0;
   Pitch_Acceleration : Real:= 0.0;
end Equations_of_Motion;
```

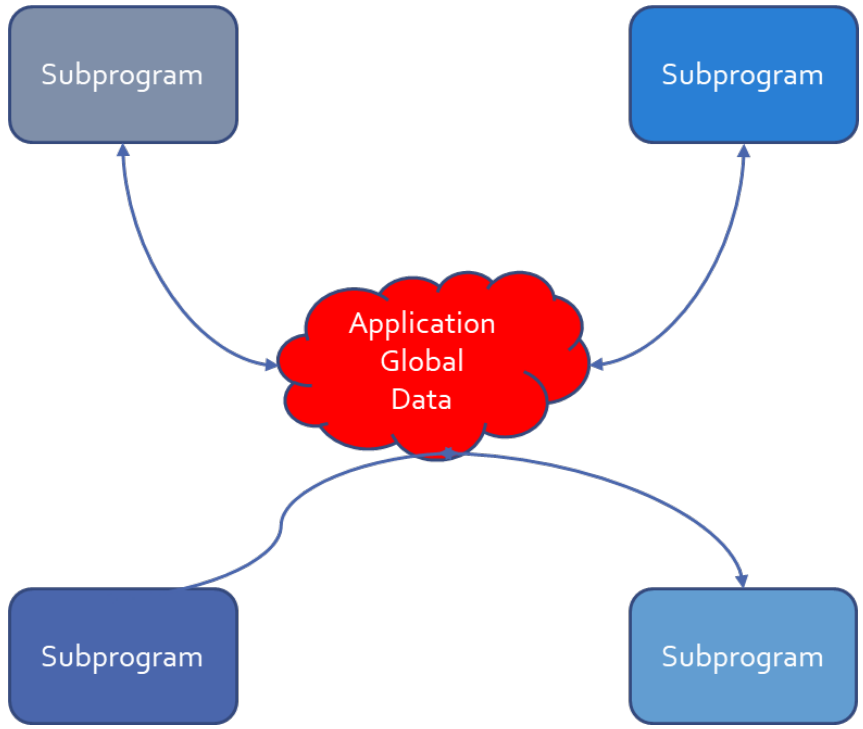
Group of Related Program Units

- Exports:
  - Objects
  - Types
  - Values
  - Operations
- Users have full access to type representations
  - This visibility may be necessary

```
package Linear_Algebra is
   type Vector is array (Positive range <>) of Real;
   function "+" (L,R : Vector) return Vector;
   function "*" (L,R : Vector) return Vector;
   ...
end Linear_Algebra;
```

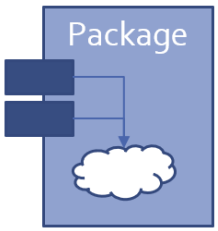
Uncontrolled Data Visibility Problem

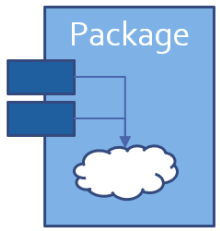
- Effects of changes are potentially pervasive so one must understand everything before changing anything

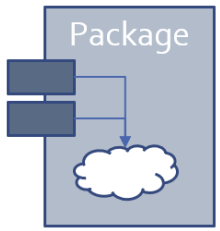


Controlling Data Visibility Using Packages

- Divides global data into separate package bodies
- Visible only to procedures and functions declared in those same packages
  - Clients can only call these visible routines
- Global change effects are much less likely
  - Direct breakage is impossible







Abstract Data Machines

- Exports:
  - Operations
  - State information queries (optional)
- No direct user access to data

```
package Float_Stack is
  Max : constant := 100;
  procedure Push (X : in Float);
  procedure Pop (X : out Float);
end Float_Stack;

package body Float_Stack is
  type Contents is array (1 .. Max) of Float;
  Values : Contents;
  Top : Integer range 0 .. Max := 0;
  procedure Push (X : in Float) is ...
  procedure Pop (X : out Float) is ...
end Float_Stack;
```

Controlling Type Representation Visibility

- In other words, support for Abstract Data Types
  - No operations visible to clients based on representation
- The fundamental concept for Ada
- Requires `private` types discussed in coming section...

Lab

Packages Lab

- Requirements
  - Create a program to add and remove integer values from a list
  - Program should allow user to do the following as many times as desired
    - Add an integer in a pre-defined range to the list
    - Remove all occurrences of an integer from the list
    - Print the values in the list
- Hints
  - Create (at least) three packages
    1. minimum/maximum integer values and maximum number of items in list
    2. User input (ensure value is in range)
    3. List ADT
  - Remember: `with package_name;` gives access to `package_name`

Creating Packages in GNAT Studio

- Right-click on the source directory node
  - If you used a prompt, the directory is probably **.**
  - If you used the wizard, the directory is probably **src**
- New → Ada Package
  - Fill in name of Ada package
  - Check the box if you want to create the package body in addition to the package spec

Packages Lab Solution - Constants

```
package Constants is

   Lowest_Value  : constant := 100;
   Highest_Value : constant := 999;
   Maximum_Count : constant := 10;
   subtype Integer_T is Integer
      range Lowest_Value .. Highest_Value;

end Constants;
```

Packages Lab Solution - Input

```
with Constants;
package Input is
   function Get_Value (Prompt : String) return Constants.Integer_T;
end Input;

with Ada.Text_IO; use Ada.Text_IO;
package body Input is

   function Get_Value (Prompt : String) return Constants.Integer_T is
      Ret_Val : Integer;
   begin
      Put (Prompt & "> ");
      loop
         Ret_Val := Integer'Value (Get_Line);
         exit when Ret_Val >= Constants.Lowest_Value
           and then Ret_Val <= Constants.Highest_Value;
         Put ("Invalid. Try Again >");
      end loop;
      return Ret_Val;
   end Get_Value;

end Input;
```

Packages Lab Solution - List

```
package List is
   procedure Add (Value : Integer);
   procedure Remove (Value : Integer);
   function Length return Natural;
   procedure Print;
end List;

with Ada.Text_IO; use Ada.Text_IO;
with Constants;
package body List is
   Content : array (1 .. Constants.Maximum_Count) of Integer;
   Last    : Natural := 0;

   procedure Add (Value : Integer) is
   begin
      if Last < Content'Last then
         Last           := Last + 1;
         Content (Last) := Value;
      else
         Put_Line ("Full");
      end if;
   end Add;

   procedure Remove (Value : Integer) is
      I : Natural := 1;
   begin
      while I <= Last loop
         if Content (I) = Value then
            Content (I .. Last - 1) := Content (I + 1 .. Last);
            Last                    := Last - 1;
         else
            I := I + 1;
         end if;
      end loop;
   end Remove;

   procedure Print is
   begin
      for I in 1 .. Last loop
         Put_Line (Integer'Image (Content (I)));
      end loop;
   end Print;

   function Length return Natural is ( Last );
end List;
```

Packages Lab Solution - Main

```
with Ada.Text_IO; use Ada.Text_IO;
with Input;
with List;
procedure Main is

begin

   loop
      Put ("(A)dd | (R)emove | (P)rint | Q(uit) : ");
      declare
         Str : constant String := Get_Line;
      begin
         exit when Str'Length = 0;
         case Str (Str'First) is
            when 'A' =>
               List.Add (Input.Get_Value ("Value to add"));
            when 'R' =>
               List.Remove (Input.Get_Value ("Value to remove"));
            when 'P' =>
               List.Print;
            when 'Q' =>
               exit;
            when others =>
               Put_Line ("Illegal entry");
         end case;
      end;
   end loop;

end Main;
```

Summary

Summary

- Emphasizes separations of concerns
- Solves the global visibility problem
  - Only those items in the specification are exported
- Enforces software engineering principles
  - Information hiding
  - Abstraction
- Implementation can't be corrupted by clients
  - Compiler won't let clients compile references to internals
- Bugs must be in the implementation, not clients
  - Only body implementation code has to be understood

Private Types

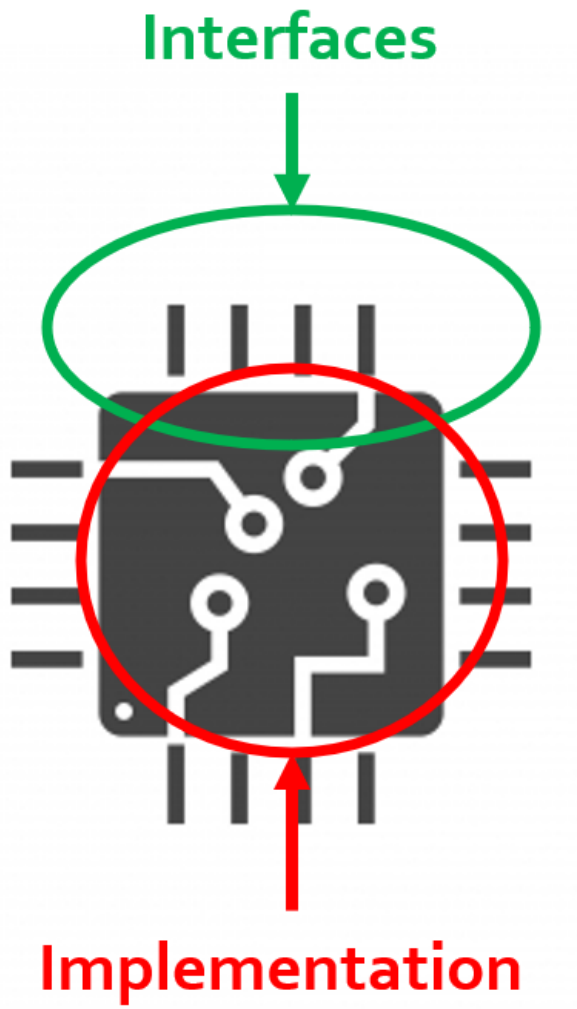
Introduction

Introduction

- Why does fixing bugs introduce new ones?
- Control over visibility is a primary factor
  - Changes to an abstraction's internals shouldn't break users
  - Including type representation
- Need tool-enforced rules to isolate dependencies
  - Between implementations of abstractions and their users
  - In other words, "information hiding"

Information Hiding

- A design technique in which implementation artifacts are made inaccessible to users
- Based on control of visibility to those artifacts
  - A product of "encapsulation"
  - Language support provides rigor
- Concept is "software integrated circuits"



Views

- Specify legal manipulation for objects of a type
  - Types are characterized by permitted values and operations
- Some views are implicit in language
  - Mode `in` parameters have a view disallowing assignment
- Views may be explicitly specified
  - Disallowing access to representation
  - Disallowing assignment
- Purpose: control usage in accordance with design
  - Adherence to interface
  - Abstract Data Types

Implementing Abstract Data Types via Views

Examples

```
package Bounded_Stack is
   Max_Capacity : constant := 100;
   type Stack_T is private;
   procedure Push (This : in out Stack_T; Item : Integer);
   procedure Pop (This : in out Stack_T; Item : out Integer);
   function Is_Empty (This : Stack_T) return Boolean;
private
   type List_T is array (1 .. Max_Capacity) of Integer;
   type Stack_T is record
      List : List_T;
      Top  : Integer range 0 .. Max_Capacity := 0;
   end record;
end Bounded_Stack;

package body Bounded_Stack is
   procedure Push (This : in out Stack_T; Item : Integer) is
   begin
      This.Top             := This.Top + 1;
      This.List (This.Top) := Item;
   end Push;
   procedure Pop (This : in out Stack_T; Item : out Integer) is
   begin
      Item     := This.List (This.Top);
      This.Top := This.Top - 1;
   end Pop;
   function Is_Empty (This : Stack_T) return Boolean is (This.Top = 0);
end Bounded_Stack;

with Ada.Text_IO;   use Ada.Text_IO;
with Bounded_Stack; use Bounded_Stack;
procedure Main is
   Stack : Stack_T;
   Item  : Integer;
begin
   Push (Stack, 42);
   Put_Line (Boolean'Image (Is_Empty (Stack)));
   Pop (Stack, Item);
   --Put_Line (Integer'Image (Stack.Top)); -- compile error
   Put_Line (Boolean'Image (Is_Empty (Stack)));
   Put_Line (Item'Image);
end Main;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/110_private_types.html#implementing-abstract-data-types-via-views

Implementing Abstract Data Types

- A combination of constructs in Ada
- Not based on single "class" construct, for example
- Constituent parts
  - Packages, with "private part" of package spec
  - "Private types" declared in packages
  - Subprograms declared within those packages

Package Visible and Private Parts for Views

- Declarations in visible part are exported to users
- Declarations in private part are hidden from users
  - No compilable references to type's actual representation

```
package name is
... exported declarations of types, variables, subprograms ...
private
... hidden declarations of types, variables, subprograms ...
end name;
```

Declaring Private Types for Views

- Partial syntax

```
type defining_identifier is private;
```

- Private type declaration must occur in visible part
  - *Partial view*
  - Only partial information on the type
  - Users can reference the type name
- Full type declaration must appear in private part
  - Completion is the *Full view*
  - **Never** visible to users
  - **Not** visible to designer until reached

```
package Control is
  type Valve is private;
  procedure Open (V : in out Valve);
  procedure Close (V : in out Valve);
  ...
private
  type Valve is ...
end Control;
```

Partial and Full Views of Types

- Private type declaration defines a *partial view*
  - The type name is visible
  - Only designer's operations and some predefined operations
  - No references to full type representation
- Full type declaration defines the *full view*
  - Fully defined as a record type, scalar, imported type, etc...
  - Just an ordinary type within the package
- Operations available depend upon one's view

Software Engineering Principles

- Encapsulation and abstraction enforced by views
  - Compiler enforces view effects
- Same protection as hiding in a package body
  - Recall "Abstract Data Machines" idiom
- Additional flexibility of types
  - Unlimited number of objects possible
  - Passed as parameters
  - Components of array and record types
  - Dynamically allocated
  - et cetera

Users Declare Objects of the Type

- Unlike "abstract data machine" approach
- Hence must specify which stack to manipulate
  - Via parameter

```
X, Y, Z : Stack;
...
Push ( 42, X );
...
if Empty ( Y ) then
...
Pop ( Counter, Z );
```

Compile-Time Visibility Protection

- No type representation details available outside the package
- Therefore users cannot compile code referencing representation
- This does not compile

```
with Bounded_Stacks;
procedure User is
   S : Bounded_Stacks.Stack;
begin
   S.Top := 1;   -- Top is not visible
end User;
```

Benefits of Views

- Users depend only on visible part of specification
  - Impossible for users to compile references to private part
  - Physically seeing private part in source code is irrelevant
- Changes to implementation don't affect users
  - No editing changes necessary for user code
- Implementers can create bullet-proof abstractions
  - If a facility isn't working, you know where to look
- Fixing bugs is less likely to introduce new ones

Quiz

```
package P is
   type Private_T is private;

   type Record_T is record
```

Which component is legal?

A. `Field_A : integer := Private_T'Pos (Private_T'First);`

B. `Field_B : Private_T := null;`

C. `Field_C : Private_T := 0;`

D. `Field_D : integer := Private_T'Size;`

```
   end record;
```

Quiz

```
package P is
   type Private_T is private;

   type Record_T is record
```

Which component is legal?

A. `Field_A : integer := Private_T'Pos (Private_T'First);`

B. `Field_B : Private_T := null;`

C. `Field_C : Private_T := 0;`

D. *`Field_D : integer := Private_T'Size;`*

```
   end record;
```

Explanations

A. Visible part does not know `Private_T` is discrete
B. Visible part does not know possible values for `Private_T`
C. Visible part does not know possible values for `Private_T`
D. Correct - type will have a known size at run-time

Private Part Construction

Examples

```
package Sets is
   type Set_T is private;
   Null_Set : constant Set_T;
   type Days_T is (Sun, Mon, Tue, Wed, Thu, Fri, Sat);
   procedure Add (This : in out Set_T; Day : Days_T);
   procedure Remove (This : in out Set_T; Day : Days_T);
   function Str (This : Set_T) return String;
private
   function Length (This : Set_T) return Natural;
   type Set_T is array (Days_T) of Boolean;
   Null_Set : constant Set_T := (others => False);
end Sets;

package body Sets is
   procedure Add (This : in out Set_T; Day : Days_T) is
   begin
      This (Day) := True;
   end Add;
   procedure Remove (This : in out Set_T; Day : Days_T) is null;
   function Str (This : Set_T) return String is
      Ret_Val : String (1 .. Length (This) * 4) := (others => ' ');
      Pos     : Natural                         := 1;
   begin
      for D in This'Range loop
         if This (D) then
            Ret_Val (Pos .. Pos + 2) := D'Image;
            Pos                      := Pos + 4;
         end if;
      end loop;
      return Ret_Val;
   end Str;
   function Length (This : Set_T) return Natural is
      Ret_Val : Natural := 0;
   begin
      for D in This'Range loop
         Ret_Val := Ret_Val + (if This (D) then 1 else 0);
      end loop;
      return Ret_Val;
   end Length;
end Sets;

with Ada.Text_IO; use Ada.Text_IO;
with Sets;        use Sets;
procedure Main is
   Set : Set_T := Null_Set;
begin
   Add (Set, Sun);
   Add (Set, Sat);
   Add (Set, Mon);
   Put_Line (Str (Set));
end Main;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/110_private_types.html#private-part-construction

Private Part Location

- Must be in package specification, not body
- Body usually compiled separately after declaration
- Users can compile their code before the package body is compiled or even written
  - Package definition

```
package Bounded_Stacks is
  type Stack is private;
  ...
private
  type Stack is ...
end Bounded_Stacks;
```

  - Package reference

```
with Bounded_Stacks;
procedure User is
  S : Bounded_Stacks.Stack;
...
begin
  ...
end User;
```

Private Part and Recompilation

- Private part is part of the specification
  - Compiler needs info from private part for users' code, e.g., storage layouts for private-typed objects
- Thus changes to private part require user recompilation
- Some vendors avoid "unnecessary" recompilation
  - Comment additions or changes
  - Additions which nobody yet references

Declarative Regions

- Declarative region of the spec extends to the body
  - Anything declared there is visible from that point down
  - Thus anything declared in specification is visible in body

```
package Foo is
   type Private_T is private;
   procedure X ( B : in out Private_T );
private
   -- Y and Hidden_T are not visible to users
   procedure Y ( B : in out Private_T );
   type Hidden_T is ...;
   type Private_T is array ( 1 .. 3 ) of Hidden_T;
end Foo;

package body Foo is
   -- Z is not visible to users
   procedure Z ( B : in out Private_T ) is ...
   procedure Y ( B : in out Private_T ) is ...
   procedure X ( B : in out Private_T ) is ...
 end Foo;
```

Full Type Declaration

- May be any type
  - Predefined or user-defined
  - Including references to imported types
- Contents of private part are unrestricted
  - Anything a package specification may contain
  - Types, subprograms, variables, etc.

```
package P is
   type T is private;
   ...
private
   type List is array (1.. 10)
      of Integer;
   function Initial
      return List;
   type T is record
     A, B : List := Initial;
   end record;
end P;
```

Deferred Constants

- Visible constants of a hidden representation
  - Value is "deferred" to private part
  - Value must be provided in private part
- Not just for private types, but usually so

```
package P is
   type Set is private;
   Null_Set : constant Set; -- exported name
   ...
private
   type Index is range ...
   type Set is array (Index) of Boolean;
   Null_Set : constant Set :=  -- definition
      (others => False);
end P;
```

Quiz

```
package P is
   type Private_T is private;
   Object_A : Private_T;
   procedure Proc ( Param : in out Private_T );
private
   type Private_T is new integer;
   Object_B : Private_T;
end package P;

package body P is
   Object_C : Private_T;
   procedure Proc ( Param : in out Private_T ) is null;
end P;
```

Which object definition is illegal?

A. `Object_A`
B. `Object_B`
C. `Object_C`
D. None of the above

Quiz

```
package P is
   type Private_T is private;
   Object_A : Private_T;
   procedure Proc ( Param : in out Private_T );
private
   type Private_T is new integer;
   Object_B : Private_T;
end package P;

package body P is
   Object_C : Private_T;
   procedure Proc ( Param : in out Private_T ) is null;
end P;
```

Which object definition is illegal?

A. *Object_A*
B. Object_B
C. Object_C
D. None of the above

An object cannot be declared until its type is fully declared. `Object_A` could be declared constant, but then it would have to be finalized in the `private` section.

View Operations

View Operations

- A matter of inside versus outside the package
  - Inside the package the view is that of the designer
  - Outside the package the view is that of the user
- **User** of package has **Partial** view
  - Operations exported by package
  - Basic operations
- **Designer** of package has **Full** view
  - **Once** completion is reached
  - All operations based upon full definition of type
  - Indexed components for arrays
  - components for records
  - Type-specific attributes
  - Numeric manipulation for numerics
  - et cetera

Designer View Sees Full Declaration

```
package Bounded_Stacks is
   Capacity : constant := 100;
   type Stack is private;
   procedure Push (Item : in Integer; Onto : in out Stack);
   ...
private
   type Index is range 0 .. Capacity;
   type List is array (Index range 1..Capacity) of Integer;
   type Stack is record
      Top : integer;
      ...
end Bounded_Stacks;
```

Designer View Allows All Operations

```
package body Bounded_Stacks is
   procedure Push (Item : in Integer;
                   Onto : in out Stack) is
   begin
      Onto.Top := Onto.Top + 1;
      ...
   end Push;

   procedure Pop (Item : out Integer;
                  From : in out Stack) is
   begin
      Onto.Top := Onto.Top - 1;
      ...
   end Pop;
end Bounded_Stacks;
```

Users Have the Partial View

- Since they are outside package
- Basic operations
- Exported subprograms

```
package Bounded_Stacks is
   type Stack is private;
   procedure Push (Item : in Integer; Onto : in out Stack);
   procedure Pop (Item : out Integer; From : in out Stack);
   function Empty (S : Stack) return Boolean;
   procedure Clear (S : in out Stack);
   function Top (S : Stack) return Integer;
private
   ...
end Bounded_Stacks;
```

User View's Activities

- Declarations of objects
  - Constants and variables
  - Must call designer's functions for values

```
C : Complex.Number := Complex.I;
```

- Assignment, equality and inequality, conversions
- Designer's declared subprograms
- User-declared subprograms
  - Using parameters of the exported private type
  - Dependent on designer's operations

User View Formal Parameters

- Dependent on designer's operations for manipulation
  - Cannot reference type's representation
- Can have default expressions of private types

```
-- external implementation of "Top"
procedure Get_Top (
    The_Stack : in out Bounded_Stacks.Stack;
    Value : out Integer) is
  Local : Integer;
begin
  Bounded_Stacks.Pop (Local, The_Stack);
  Value := Local;
  Bounded_Stacks.Push (Local, The_Stack);
end Get_Top;
```

Private Limited

- `limited` is itself a view
  - Cannot perform assignment, copy, or equality
- `private limited` can restrain user's operation
  - Actual type **does not** need to be `limited`

```
package UART is
    type Instance is private limited;
    function Get_Next_Available return Instance;
[...]

declare
   A, B := UART.Get_Next_Available;
begin
   if A = B -- Illegal
   then
       A := B; -- Illegal
   end if;
```

When To Use or Avoid Private Types

When To Use Private Types

- Implementation may change
  - Allows users to be unaffected by changes in representation
- Normally available operations do not "make sense"
  - Normally available based upon type's representation
  - Determined by intent of ADT

```
A : Valve;
B : Valve;
C : Valve;
...
C := A + B;   -- addition not meaningful
```

- Users have no "need to know"
  - Based upon expected usage

When To Avoid Private Types

- If the abstraction is too simple to justify the effort
  - But that's the thinking that led to Y2K rework
- If normal user interface requires representation-specific operations that cannot be provided
  - Those that cannot be redefined by programmers
  - Would otherwise be hidden by a private type
  - If **Vector** is private, indexing of elements is annoying

```
type Vector is array (Positive range <>) of Real;
V : Vector (1 .. 3);
...
V (1) := Alpha;
```

Idioms

Examples

```
package Complex is
   type Number_T is private;
   function Constructor (Real_Part, Imaginary_Part : Float )
                         return Number_T;
   procedure Constructor (This           : out Number_T;
                          Real_Part      :     Float;
                          Imaginary_Part :     Float);
   function Real_Part (This : Number_T) return Float;
   function Imaginary_Part (This : Number_T) return Float;
   function Str (This : Number_T) return String;

private
   type Number_T is record
      Real_Part, Imaginary_Part : Float;
   end record;

   function Constructor (Real_Part, Imaginary_Part : Float )
                         return Number_T is
      (Real_Part, Imaginary_Part);

   function Real_Part (This : Number_T) return Float is
     (This.Real_Part);
   function Imaginary_Part (This : Number_T) return Float is
     (This.Imaginary_Part);
end Complex;

package body Complex is
   procedure Constructor (This           : out Number_T;
                          Real_Part      :     Float;
                          Imaginary_Part :     Float) is
   begin
      This := Constructor (Real_Part, Imaginary_Part);
   end Constructor;

   function Str (This : Number_T) return String is
   begin
      return Float'Image (Real_Part (This)) & " " &
        Float'Image (Imaginary_Part (This)) & "i";
   end Str;
end Complex;

with Ada.Text_IO; use Ada.Text_IO;
with Complex;     use Complex;
procedure Main is
   Number : Number_T := Constructor (1.2, 3.4);
begin
   Put_Line (Str (Number));
   Constructor (Number, 56.7, 8.9);
   Put_Line (Str (Number));
end Main;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/110_private_types.html#idioms

Effects of Hiding Type Representation

- Makes users independent of representation
  - Changes cannot require users to alter their code
  - Software engineering is all about money...
- Makes users dependent upon exported operations
  - Because operations requiring representation info are not available to users
    - Expression of values (aggregates, etc.)
    - Assignment for limited types
- Common idioms are a result
  - *Constructor*
  - *Selector*

Constructors

- Create designer's objects from user's values
- Usually functions

```
package Complex is
   type Number is private;
   function Make (Real_Part : Float; Imaginary : Float) return Number
private
   type Number is record ...
end Complex;

package body Complex is
    function Make (Real_Part : Float; Imaginary_Part : Float)
      return Number is ...
end Complex:
...
A : Complex.Number :=
    Complex.Make (Real_Part => 2.5, Imaginary => 1.0);
```

Procedures As Constructors

- Spec

```
package Complex is
  type Number is private;
  procedure Make (This : out Number;  Real_Part, Imaginary : in Float) ;
  ...
private
  type Number is record
    Real_Part, Imaginary : Float;
  end record;
end Complex;
```

- Body (partial)

```
package body Complex is
  procedure Make (This : out Number;
                  Real_Part, Imaginary : in Float) is
    begin
      This.Real_Part := Real_Part;
      This.Imaginary := Imaginary;
    end Make;
...
```

Selectors

- Decompose designer's objects into user's values
- Usually functions

```
package Complex is
  type Number is private;
  function Real_Part (This: Number) return Float;
  ...
private
  type Number is record
    Real_Part, Imaginary : Float;
  end record;
end Complex;

package body Complex is
  function Real_Part (This : Number) return Float is
  begin
    return This.Real_Part;
  end Real_Part;
  ...
end Complex;
...
Phase : Complex.Number := Complex.Make (10.0, 5.5);
Object : Float := Complex.Real_Part (Phase);
```

Lab

Private Types Lab

- Requirements
  - Implement a program to create a map such that
    - Map key is a description of a flag
    - Map element content is the set of colors in the flag
  - Operations on the map should include: Add, Remove, Modify, Get, Exists, Image
  - Main program should print out the entire map before exiting
- Hints
  - Should implement a **map** ADT (to keep track of the flags)
    - This **map** will contain all the flags and their color descriptions
  - Should implement a **set** ADT (to keep track of the colors)
    - This **set** will be the description of the map element
  - Each ADT should be its own package
  - At a minimum, the **map** and **set** type should be **private**

Private Types Lab Solution - Color Set

```
package Colors is
   type Color_T is (Red, Yellow, Green, Blue, Black);
   type Color_Set_T is private;

   Empty_Set : constant Color_Set_T;

   procedure Add (Set   : in out Color_Set_T;
                  Color :        Color_T);
   procedure Remove (Set   : in out Color_Set_T;
                     Color :        Color_T);
   function Image (Set : Color_Set_T) return String;
private
   type Color_Set_Array_T is array (Color_T) of Boolean;
   type Color_Set_T is record
      Values : Color_Set_Array_T := (others => False);
   end record;
   Empty_Set : constant Color_Set_T := (Values => (others => False));
end Colors;

package body Colors is
   procedure Add (Set   : in out Color_Set_T;
                  Color :        Color_T) is
   begin
      Set.Values (Color) := True;
   end Add;
   procedure Remove (Set   : in out Color_Set_T;
                     Color :        Color_T) is
   begin
      Set.Values (Color) := False;
   end Remove;

   function Image (Set   : Color_Set_T;
                   First : Color_T;
                   Last  : Color_T)
                   return String is
      Str : constant String := (if Set.Values (First) then Color_T'Image (First) else "");
   begin
      if First = Last then
         return Str;
      else
         return Str & " " & Image (Set, Color_T'Succ (First), Last);
      end if;
   end Image;
   function Image (Set : Color_Set_T) return String is
      ( Image (Set, Color_T'First, Color_T'Last) );
end Colors;
```

Private Types Lab Solution - Flag Map (Spec)

```
with Colors;
package Flags is
   type Key_T is (USA, England, France, Italy);
   type Map_Element_T is private;
   type Map_T is private;

   procedure Add (Map         : in out Map_T;
                  Key         :        Key_T;
                  Description :        Colors.Color_Set_T;
                  Success     :    out Boolean);
   procedure Remove (Map     : in out Map_T;
                     Key     :        Key_T;
                     Success :    out Boolean);
   procedure Modify (Map         : in out Map_T;
                     Key         :        Key_T;
                     Description :        Colors.Color_Set_T;
                     Success     :    out Boolean);

   function Exists (Map : Map_T; Key : Key_T) return Boolean;
   function Get (Map : Map_T; Key : Key_T) return Map_Element_T;
   function Image (Item : Map_Element_T) return String;
   function Image (Flag : Map_T) return String;
private
   type Map_Element_T is record
      Key         : Key_T := Key_T'First;
      Description : Colors.Color_Set_T := Colors.Empty_Set;
   end record;
   type Map_Array_T is array (1 .. 100) of Map_Element_T;
   type Map_T is record
      Values : Map_Array_T;
      Length : Natural := 0;
   end record;
end Flags;
```

Private Types Lab Solution - Flag Map (Body - 1 of 2)

```
procedure Add (Map         : in out Map_T;
               Key         :        Key_T;
               Description :        Colors.Color_Set_T;
               Success     :    out Boolean) is
begin
   Success := (for all Item of Map.Values
        (1 .. Map.Length) => Item.Key /= Key);
   if Success then
      declare
         New_Item : constant Map_Element_T :=
           (Key => Key, Description => Description);
      begin
         Map.Length              := Map.Length + 1;
         Map.Values (Map.Length) := New_Item;
      end;
   end if;
end Add;
procedure Remove (Map     : in out Map_T;
                  Key     :        Key_T;
                  Success :    out Boolean) is
begin
   Success := False;
   for I in 1 .. Map.Length loop
      if Map.Values (I).Key = Key then
         Map.Values
           (I .. Map.Length - 1) := Map.Values
             (I + 1 .. Map.Length);
         Map.Length := Map.Length - 1;
         Success := True;
         exit;
      end if;
   end loop;
end Remove;
```

Private Types Lab Solution - Flag Map (Body - 2 of 2)

```
procedure Modify (Map         : in out Map_T;
                  Key         :        Key_T;
                  Description :        Colors.Color_Set_T;
                  Success     :    out Boolean) is
begin
   Success := False;
   for I in 1 .. Map.Length loop
      if Map.Values (I).Key = Key then
         Map.Values (I).Description := Description;
         Success                    := True;
         exit;
      end if;
   end loop;
end Modify;
function Exists (Map : Map_T; Key : Key_T) return Boolean is
   (for some Item of Map.Values (1 .. Map.Length) => Item.Key = Key);

  (Key_T'Image (Item.Key) & " => " & Colors.Image (Item.Description));
function Image (Flag : Map_T) return String is
   Ret_Val : String (1 .. 1_000);
   Next    : Integer := Ret_Val'First;
begin
   for Item of Flag.Values (1 .. Flag.Length) loop
      declare
         Str : constant String := Image (Item);
      begin
         Ret_Val (Next .. Next + Str'Length) := Image (Item) & ASCII.LF;
         Next                                := Next + Str'Length + 1;
      end;
   end loop;
   return Ret_Val (1 .. Next - 1);
end Image;
```

Private Types Lab Solution - Main

```
with Ada.Text_IO; use Ada.Text_IO;
with Colors;
with Flags;
with Input;
procedure Main is
   Map : Flags.Map_T;
begin

   loop
      Put ("Enter country name (");
      for Key in Flags.Key_T loop
         Put (Flags.Key_T'Image (Key) & " ");
      end loop;
      Put ("): ");
      declare
         Str         : constant String := Get_Line;
         Key         : Flags.Key_T;
         Description : Colors.Color_Set_T;
         Success     : Boolean;
      begin
         exit when Str'Length = 0;
         Key         := Flags.Key_T'Value (Str);
         Description := Input.Get;
         if Flags.Exists (Map, Key) then
            Flags.Modify (Map, Key, Description, Success);
         else
            Flags.Add (Map, Key, Description, Success);
         end if;
      end;
   end loop;

   Put_Line (Flags.Image (Map));
end Main;
```

Summary

Summary

- Tool-enforced support for Abstract Data Types
  - Same protection as Abstract Data Machine idiom
  - Capabilities and flexibility of types
- May also be `limited`
  - Thus additionally no assignment or predefined equality
  - More on this later
- Common interface design idioms have arisen
  - Resulting from representation independence
- Assume private types as initial design choice
  - Change is inevitable

Program Structure

Introduction

Introduction

- Moving to "bigger" issues of overall program composition
- How to compose programs out of program units
- How to control object lifetimes
- How to define subsystems

Building A System

What is a System?

- Also called Application or Program or ...
- Collection of *library units*
  - Which are a collection of packages, subprograms, objects

Library Units Review

- Those units not nested within another program unit
- Candidates
  - Subprograms
  - Packages
  - Generic Units
  - Generic Instantiations
  - Renamings
- Dependencies between library units via `with` clauses
  - What happens when two units need to depend on each other?

"limited with" Clauses

Examples

```
limited with Department;
package Personnel is
   type Employee_T is private;
   procedure Assign (This : in out Employee_T; Section : in Department.Section_T);
private
   type Employee_T is record
      Name        : String (1 .. 10);
      Assigned_To : access Department.Section_T;
   end record;
end Personnel;

limited with Personnel;
package Department is
   type Section_T is private;
   procedure Set_Manager (This : in out Section_T; Who : in Personnel.Employee_T);
private
   type Section_T is record
      Name    : String (1 .. 10);
      Manager : access Personnel.Employee_T;
   end record;
end Department;

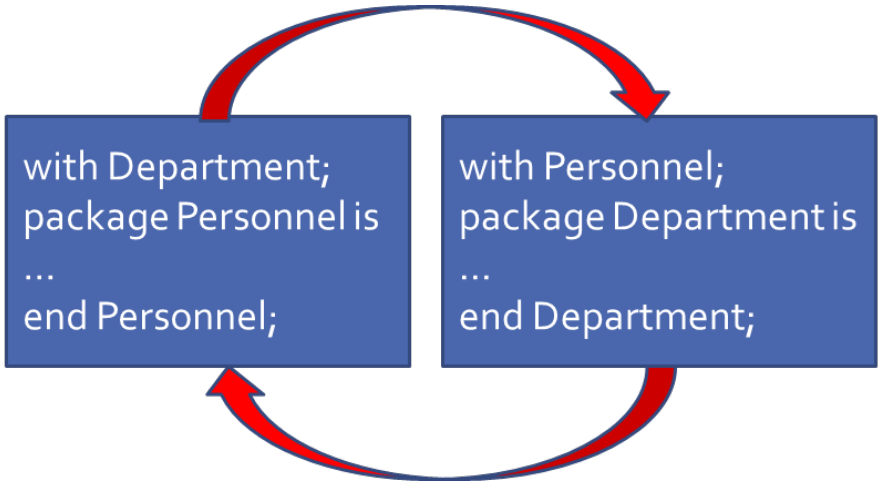
with Department;
package body Personnel is
   procedure Assign (This : in out Employee_T; Section : in Department.Section_T) is
   begin
      This.Assigned_To.all := Section;
   end Assign;
end Personnel;

with Personnel;
package body Department is
   procedure Set_Manager (This : in out Section_T; Who : in Personnel.Employee_T) is
   begin
      This.Manager.all := Who;
   end Set_Manager;
end Department;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/130_program_structure.html#limited-with-clauses

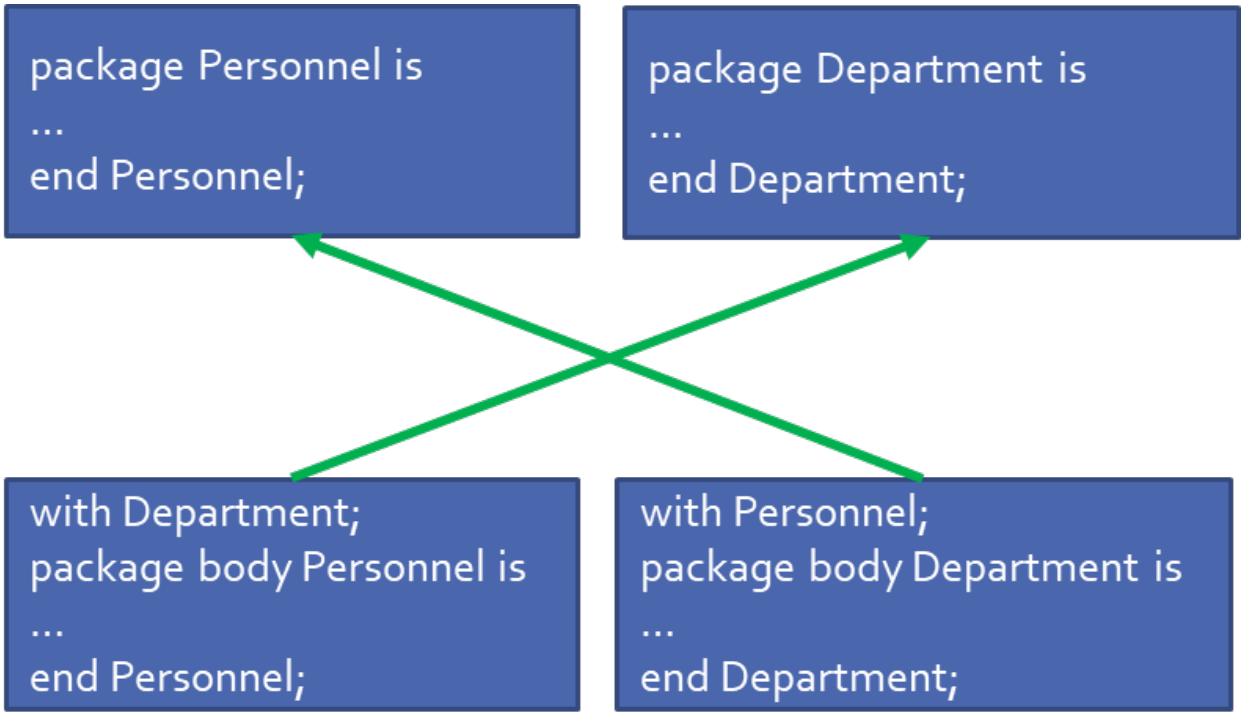
Handling Cyclic Dependencies

- Elaboration must be linear
- Package declarations cannot depend on each other
  - No linear order is possible
- Which package elaborates first?



Body-Level Cross Dependencies Are OK

- The bodies only depend on other packages' declarations
- The declarations are already elaborated by the time the bodies are elaborated



Resulting Design Problem

- Good design dictates that conceptually distinct types appear in distinct package declarations
  - Separation of concerns
  - High level of *cohesion*
- Not possible if they depend on each other
- One solution is to combine them in one package, even though conceptually distinct
  - Poor software engineering

Illegal Package Declaration Dependency

```
with Department;
package Personnel is
  type Employee is private;
  procedure Assign ( This : in Employee;
                     To : in out Department.Section);
private
  type Employee is record
    Assigned_To : Department.Section;
  end record;
end Personnel;

with Personnel;
package Department is
  type Section is private;
  procedure Choose_Manager ( This : in out Section;
                             Who : in Personnel.Employee);
private
  type Section is record
    Manager : Personnel.Employee;
  end record;
end Department;
```

limited with Clauses

Ada 2005

- Solve the cyclic declaration dependency problem
  - Controlled cycles are now permitted
- Provide a *limited view* of the specified package
  - Only type names are visible (including in nested packages)
  - Types are viewed as *incomplete types*
- Normal view

```
package Personnel is
  type Employee is private;
  procedure Assign ...
private
  type Employee is ...
end Personnel;
```

- Implied limited view

```
package Personnel is
  type Employee;
end Personnel;
```

Using Incomplete Types

- Anywhere that the compiler doesn't yet need to know how they are really represented
  - Access types designating them
  - Access parameters designating them
  - Anonymous access components designating them
  - As formal parameters and function results
    - As long as compiler knows them at the point of the call
  - As generic formal type parameters
  - As introductions of private types
- If `tagged`, may also use **'Class**
- Thus typically involves some advanced features

Legal Package Declaration Dependency

Ada 2005

```
limited with Department;
package Personnel is
  type Employee is private;
  procedure Assign ( This : in Employee;
                     To : in out Department.Section);
private
  type Employee is record
    Assigned_To : access Department.Section;
  end record;
end Personnel;

limited with Personnel;
package Department is
  type Section is private;
  procedure Choose_Manager ( This : in out Section;
                             Who : in Personnel.Employee);
private
  type Section is record
    Manager : access Personnel.Employee;
  end record;
end Department;
```

Full **with** Clause On the Package Body

Ada 2005

- Even though declaration has a `limited with` clause
- Typically necessary since body does the work
  - Dereferencing, etc.
- Usual semantics from then on

```
limited with Personnel;
package Department is
...
end Department;

with Personnel; -- normal view in body
package body Department is
...
end Department;
```

Hierarchical Library Units

Examples

```
package Complex is
   type Number is private;
   function "+" (Left, Right : Number) return Number;
   function "-" (Left, Right : Number) return Number;
private
   type Number is record
      Real_Part, Imaginary_Part : Float;
   end record;
end Complex;

package Complex.Utils is
   function To_String (C : Number) return String;
end Complex.Utils;

package body Complex.Utils is
   -- construction of "number" is visible in the child body
   function To_String (C : Number) return String is
     (C.Real_Part'Image & " + i" & C.Imaginary_Part'Image);
end Complex.Utils;

package Complex.Debug is
   -- "with Complex;" not needed for visibility to Number
   procedure Print (C : Number);
end Complex.Debug;

with Ada.Text_IO;
with Complex.Utils; -- needed for visibility to "To_String"
package body Complex.Debug is
   procedure Print (C : Number) is
   begin
      -- because of parent visibility, don't need to use "Complex.Utils"
      Ada.Text_IO.Put_Line (Utils.To_String (C));
   end Print;
end Complex.Debug;

package body Complex is
   function "+" (Left, Right : Number) return Number is (Left);
   function "-" (Left, Right : Number) return Number is (Left);
end Complex;
```

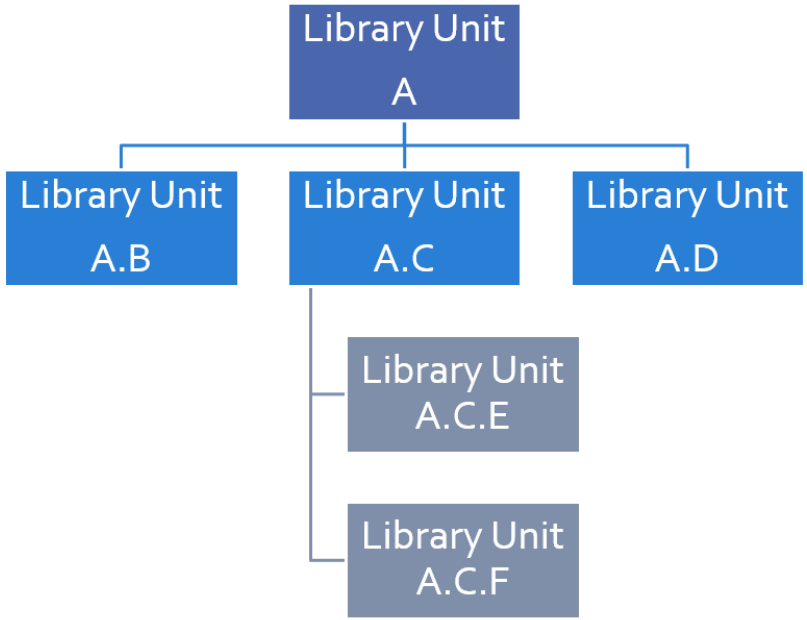
https://learn.adacore.com/training_examples/fundamentals_of_ada/130_program_structure.html#hierarchical-library-units

Problem: Packages Are Not Enough

- Extensibility is a problem for private types
  - Provide excellent encapsulation and abstraction
  - But one has either complete visibility or essentially none
  - New functionality must be added to same package for sake of compile-time visibility to representation
  - Thus enhancements require editing/recompilation/retesting
- Should be something "bigger" than packages
  - Subsystems
  - Directly relating library items in one name-space
    - One big package has too many disadvantages
  - Avoiding name clashes among independently-developed code

Solution: Hierarchical Library Units

- Address extensibility issue
  - Can extend packages with visibility to parent private part
  - Extensions do not require recompilation of parent unit
  - Visibility of parent's private part is protected
- Directly support subsystems
  - Extensions all have the same ancestor *root* name



Programming By Extension

- *Parent unit*

```
package Complex is
  type Number is private;
  function "*" ( Left, Right : Number ) return Number;
  function "/" ( Left, Right : Number ) return Number;
  function "+" ( Left, Right : Number ) return Number;
  function "-" ( Left, Right : Number ) return Number;
...
private
  type Number is record
    Real_Part, Imaginary_Part : Float;
  end record;
end Complex;
```

- Extension created to work with parent unit

```
package Complex.Utils is
  procedure Put (C : in Number);
  function As_String (C : Number) return String;
  ...
end Complex.Utils;
```

Extension Can See Private Section

- With certain limitations

```
with Ada.Text_IO;
package body Complex.Utils is
  procedure Put( C : in Number ) is
  begin
    Ada.Text_IO.Put( As_String(C) );
  end Put;
  function As_String( C : Number ) return String is
  begin
    -- Real_Part and Imaginary_Part are
    -- visible to child's body
    return "( " & Float'Image(C.Real_Part) & ", " &
           Float'Image(C.Imaginary_Part) & " )";
  end As_String;
...
end Complex.Utils;
```

Subsystem Approach

```
with Interfaces.C;
package OS is -- Unix and/or POSIX
 type File_Descriptor is new Interfaces.C.int;
  ...
end OS;

package OS.Mem_Mgmt is
  ...
  procedure Dump ( File                : File_Descriptor;
                   Requested_Location : System.Address;
                   Requested_Size     : Interfaces.C.Size_T );
  ...
end OS.Mem_Mgmt;

package OS.Files is
  ...
  function Open ( Device : Interfaces.C.char_array;
                  Permission : Permissions := S_IRWXO )
                  return File_Descriptor;
  ...
end OS.Files;
```

Predefined Hierarchies

- Standard library facilities are children of **Ada**
  - **Ada.Text_IO**
  - **Ada.Calendar**
  - **Ada.Command_Line**
  - **Ada.Exceptions**
  - et cetera
- Other root packages are also predefined
  - **Interfaces.C**
  - **Interfaces.Fortran**
  - **System.Storage_Pools**
  - **System.Storage_Elements**
  - et cetera

Hierarchical Visibility

- Children can see ancestors' visible and private parts
  - All the way up to the root library unit
- Siblings have no automatic visibility to each other
- Visibility same as nested
  - As if child library units are nested within parents
    - All child units come after the root parent's specification
    - Grandchildren within children, great-grandchildren within ...

Example of Visibility As If Nested

```
package Complex is
  type Number is private;
  function "*" (Left, Right : Number) return Number;
  function "/" (Left, Right : Number) return Number;
  function "+" (Left, Right : Number) return Number;
  ...
private
  type Number is record
    Real_Part : Float;
    Imaginary : Float;
  end record;
  package Utils is
    procedure Put (C : in Number);
    function As_String (C : Number) return String;
    ...
  end Utils;
end Complex;
```

with Clauses for Ancestors are Implicit

- Because children can reference ancestors' private parts
  - Code is not in executable unless somewhere in the `with` clauses
- Explicit clauses for ancestors are redundant but OK

```
package Parent is
   ...
private
   A : Integer := 10;
end Parent;

-- no "with" of parent needed
package Parent.Child is
    ...
private
   B : Integer := Parent.A;
   -- no dot-notation needed
   C : integer := A;
end Parent.Child;
```

with Clauses for Siblings are Required

- If references are intended

```
with A.Foo; --required
package body A.Bar is
   ...
   -- 'Foo' is directly visible because of the
   -- implied nesting rule
   X : Foo.Typemark;
end A.Bar;
```

Quiz

```
package Parent is
   Parent_Object : Integer;
end Parent;

package Parent.Sibling is
   Sibling_Object : Integer;
end Parent.Sibling;

package Parent.Child is
   Child_Object : Integer := ? ;
end Parent.Child;
```

Which is not a legal initialization of Child_Object?

A. `Parent.Parent_Object + Parent.Sibling.Sibling_Object`
B. `Parent_Object + Sibling.Sibling_Object`
C. `Parent_Object + Sibling_Object`
D. All of the above

Quiz

```
package Parent is
   Parent_Object : Integer;
end Parent;

package Parent.Sibling is
   Sibling_Object : Integer;
end Parent.Sibling;

package Parent.Child is
   Child_Object : Integer := ? ;
end Parent.Child;
```

Which is not a legal initialization of Child_Object?

A. `Parent.Parent_Object + Parent.Sibling.Sibling_Object`
B. `Parent_Object + Sibling.Sibling_Object`
C. `Parent_Object + Sibling_Object`
D. ***All of the above***

A, B, and C are illegal because there is no reference to package `Parent.Sibling` (the reference to `Parent` is implied by the hierarchy). If `Parent.Child` had "`with Parent.Sibling;`", then A and B would be legal, but C would still be incorrect because there is no implied reference to a sibling.

Visibility Limits

Examples

```
package Stack is
   procedure Push (Item : in Integer);
   procedure Pop (Item : out Integer);
private
   Object : array (1 .. 100) of integer;
   Top    : Natural := 0;
end Stack;

package Stack.Utils is
   function Top return Integer;
private
   -- Legal here, but not above "private"
   function Top return Integer is (Object (Stack.Top));
end Stack.Utils;

package Stack.Child is
   procedure Misbehave;
   procedure Reset;
   function Peek (Index : Natural) return Integer;
end Stack.Child;

package body Stack.Child is
   procedure Misbehave is
   begin
      Top := 0;
   end Misbehave;

   procedure Reset is
   begin
      Top := 0;
   end Reset;

   function Peek (Index : Natural) return Integer is (Object (Index));
end Stack.Child;

package body Stack is
   procedure Push (Item : in Integer) is null;
   procedure Pop (Item : out Integer) is null;
end Stack;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/130_program_structure.html#visibility-limits

Parents Do Not Know Their Children!

- Children grant themselves access to ancestors' private parts
  - May be created well after parent
  - Parent doesn't know if/when child packages will exist
- Alternative is to grant access when declared
  - Like `friend` units in C++
  - But would have to be prescient!
    - Or else adding children requires modifying parent
  - Hence too restrictive
- Note: Parent body can reference children
  - Typical method of parsing out complex processes

Correlation to C++ Class Visibility Controls

- Ada private part is visible to child units

```
package P is
   A ...
private
   B ...
end P;
package body P is
   C ...
end P;
```

- Thus private part is like the protected part in C++

```
class C {
public:
   A ...
protected:
   B ...
private:
   C ...
};
```

Visibility Limits

- Visibility to parent's private part is not open-ended
  - Only visible to private parts and bodies of children
  - As if only private part of child package is nested in parent
- Recall users can only reference exported declarations
  - Child public spec only has access to parent public spec

```
package Parent is
   ...
private
   type Parent_T is ...
end Parent;

package Parent.Child is
  -- Parent_T is not visible here!
private
  -- Parent_T is visible here
end Parent.Child;

package body Parent.Child is
 -- Parent_T is visible here
end Parent.Child;
```

Children Can Break Abstraction

- Could **break** a parent's abstraction
  - Alter a parent package state
  - Alters an ADT object state
- Useful for reset, testing: fault injections...

```
package Stack is
   ...
private
   Values : array (1 .. N ) of Foo;
   Top : Natural range 0 .. N := 0
end Stack;

package body Stack.Reset is
   procedure Reset is
   begin
     Top := 0;
   end Reset;
end Stack.Tools;
```

Using Children for Debug

- Provide **accessors** to parent's private information
- eg internal metrics...

```
package P is
   ...
private
  Internal_Counter : Integer := 0;
end P;

package P.Child is
  function Count return Integer;
end P.Child;

package body P.Child is
  function Count return Integer is
  begin
    return Internal_Counter;
  end Count;
end P.Child;
```

Quiz

```
package P is
   procedure Initialize;
   Object_A : Integer;
private
   Object_B : Integer;
end P;

package body P is
   Object_C : Integer;
   procedure Initialize is null;
end P;

package P.Child is
   function X return Integer;
end P.Child;
```

Which return statement would be illegal in P.Child.X?

A. `return Object_A;`
B. `return Object_B;`
C. `return Object_C;`
D. None of the above

Quiz

```
package P is
   procedure Initialize;
   Object_A : Integer;
private
   Object_B : Integer;
end P;

package body P is
   Object_C : Integer;
   procedure Initialize is null;
end P;

package P.Child is
   function X return Integer;
end P.Child;
```

Which return statement would be illegal in P.Child.X?

A. `return Object_A;`
B. `return Object_B;`
C. *`return Object_C;`*
D. None of the above

Explanations

A. `Object_A` is in the public part of `P` - visible to any unit that `with`'s `P`
B. `Object_B` is in the private part of `P` - visible in the private part or body of any descendant of `P`
C. `Object_C` is in the body of `P`, so it is only visible in the body of `P`
D. A and B are both valid completions

Private Children

Examples

```
package Os is
   type File_T is private;
   function Open (Name : String) return File_T;
   procedure Write (File : File_T; Str : String);
   procedure Close (File : File_T);
private
   type File_T is new Integer;
end Os;

private package Os.Uart is
   type Device_T is private;
   function Open (Name : String) return Device_T;
   procedure Write (Device : Device_T; Str : String);
   procedure Close (Device : Device_T);
private
   type Device_T is new Integer;
end Os.Uart;

private with Os.Uart; -- references only in private section
private package Os.Serial is
   type Comport_T is private;
   procedure Initialize (Comport : in out Comport_T);
private
   type Comport_T is record
      Device : Uart.Device_T;
   end record;
end Os.Serial;

package body Os is
   function Open (Name : String) return File_T is (1);
   procedure Write (File : File_T; Str : String) is null;
   procedure Close (File : File_T) is null;
end Os;

package body Os.Uart is
   function Open (Name : String) return Device_T is (1);
   procedure Write (Device : Device_T; Str : String) is null;
   procedure Close (Device : Device_T) is null;
end Os.Uart;

package body Os.Serial is
   procedure Initialize (Comport : in out Comport_T) is null;
end Os.Serial;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/130_program_structure.html#private-children

Private Children

- Intended as implementation artifacts
- Only available within subsystem
  - Rules prevent `with` clauses by clients
  - Thus cannot export anything outside subsystem
  - Thus have no parent visibility restrictions
    - Public part of child also has visibility to ancestors' private parts

```
private package Maze.Debug is
   procedure Dump_State;
   ...
end Maze.Debug;
```

Rules Preventing Private Child Visibility

- Only available within immediate family
  - Rest of subsystem cannot import them
- Public unit declarations have import restrictions
  - To prevent re-exporting private information
- Public unit bodies have no import restrictions
  - Since can't re-export any imported info
- Private units can import anything
  - Declarations and bodies can import public and private units
  - Cannot be imported outside subsystem so no restrictions

Import Rules

- Only parent of private unit and its descendants can import a private child
- Public unit declarations import restrictions
  - Not allowed to have `with` clauses for private units
    - Exception explained in a moment
  - Precludes re-exporting private information
- Private units can import anything
  - Declarations and bodies can import private children

Some Public Children Are Trustworthy

- Would only use a private sibling's exports privately
- But rules disallow `with` clause

```
private package OS.UART is
 type Device is limited private;
 procedure Open (This : out Device; ...);
 ...
end OS.UART;

-- illegal - private child
with OS.UART;
package OS.Serial is
  type COM_Port is limited private;
  ...
private
  type COM_Port is limited record
    -- but I only need it here!
    COM : OS.UART.Device;
  ...
  end record;
end OS.Serial;
```

Solution 1: Move Type To Parent Package

```
package OS is
   ...
private
   -- no longer an ADT!
   type Device is limited private;
...
end OS;
private package OS.UART is
   procedure Open (This : out Device;
    ...);
   ...
end OS.UART;

package OS.Serial is
   type COM_Port is limited private;
   ...
private
   type COM_Port is limited record
     COM : Device; -- now visible
     ...
   end record;
end OS.Serial;
```

Solution 2: Partially Import Private Unit

Ada 2005

- Via `private with` clause
- Syntax

```
private with package_name {, package_name} ;
```

- Public declarations can then access private siblings
  - But only in their private part
  - Still prevents exporting contents of private unit
- The specified package need not be a private unit
  - But why bother otherwise

private with Example

Ada 2005

```
private package OS.UART is
  type Device is limited private;
  procedure Open (This : out Device;
     ...);
  ...
end OS.UART;

private with OS.UART;
package OS.Serial is
  type COM_Port is limited private;
  ...
private
  type COM_Port is limited record
    COM : OS.UART.Device;
    ...
  end record;
end OS.Serial;
```

Combining Private and Limited Withs

Ada 2005

- Cyclic declaration dependencies allowed
- A public unit can `with` a private unit
- With-ed unit only visible in the private part

```
limited with Parent.Public_Child;
private package Parent.Private_Child is
   type T is ...
end Parent.Private_Child;

limited private with Parent.Private_Child;
package Parent.Public_Child is
   ...
private
   X : access Parent.Private_Child.T;
end Parent.Public_Child;
```

Completely Hidden Declarations

- Anything in a package body is completely hidden
  - Children have no access to package bodies
- Precludes extension using the entity
  - Must know that children will never need it

```
package body Skippy is
   X : Integer := 0;
   ...
end Skippy;
```

Child Subprograms

- Child units can be subprograms
  - Recall syntax
  - Both public and private child subprograms
- Separate declaration required if private
  - Syntax doesn't allow `private` on subprogram bodies
- Only library packages can be parents
  - Only they have necessary scoping

```
private procedure Parent.Child;
```

Lab

Program Structure Lab

- Requirements
  - Create a simplistic messaging subsystem
    - Top-level should define a (private) message type and constructor/accessor subprograms
    - Use private child function to calculate message CRC
    - Use child package to add/remove messages to some kind of list
  - Use child package for diagnostics
    - Inject bad CRC into a message
    - Print message contents
  - Main program should
    - Build a list of messages
    - Inject faults into list
    - Print messages in list and indicate if any are faulty

Program Structure Lab Solution - Messages

```
with Ada.Strings.Unbounded; use Ada.Strings.Unbounded;
package Messages is
   type Message_T is private;
   type Kind_T is (Command, Query);
   subtype Content_T is String;

   function Create (Kind    : Kind_T;
                    Content : Content_T)
                    return Message_T;

   function Kind (Message : Message_T) return Kind_T;
   function Content (Message : Message_T) return Content_T;
private
   type Crc_T is mod Integer'Last;
   type Message_T is record
      Kind    : Kind_T;
      Content : Unbounded_String;
      Crc     : Crc_T;
   end record;
end Messages;

with Messages.Crc;
package body Messages is
   function Create (Kind    : Kind_T;
                    Content : Content_T)
                    return Message_T is
   begin
      return (Kind => Kind,
              Content => To_Unbounded_String (Content),
              Crc       => Crc (Content));
   end Create;

   function Kind (Message : Message_T) return Kind_T is (Message.Kind);
   function Content (Message : Message_T) return Content_T is (To_String (Message.Content));
end Messages;
```

Program Structure Lab Solution - Message Queue

```
package Messages.Queue is
   function Empty return Boolean;
   function Full return Boolean;

   procedure Push (Message : Message_T);
   procedure Pop (Message : out Message_T;
                  Valid   : out Boolean);
private
   The_Queue : array (1 .. 10) of Message_T;
   Top       : Integer := 0;
   function Empty return Boolean is (Top = 0);
   function Full return Boolean is (Top = The_Queue'Last);
end Messages.Queue;

with Messages.Crc;
package body Messages.Queue is
   procedure Push (Message : Message_T) is
   begin
      Top             := Top + 1;
      The_Queue (Top) := Message;
   end Push;

   procedure Pop (Message : out Message_T;
                  Valid   : out Boolean) is
   begin
      Message := The_Queue (Top);
      Top     := Top - 1;
      Valid   := Message.Crc = Crc (To_String (Message.Content));
   end Pop;
end Messages.Queue;
```

Program Structure Lab Solution - Diagnostics

```
package Messages.Queue.Debug is
   function Queue_Length return Integer;
   procedure Inject_Crc_Fault (Position : Integer);
   function Text (Message : Message_T) return String;
end Messages.Queue.Debug;

package body Messages.Queue.Debug is
   function Queue_Length return Integer is (Top);

   procedure Inject_Crc_Fault (Position : Integer) is
   begin
      The_Queue (Position).Crc := The_Queue (Position).Crc + 1;
   end Inject_Crc_Fault;

   function Text (Message : Message_T) return String is
     (Kind_T'Image (Message.Kind) & " => " & To_String (Message.Content) &
      " (" & Crc_T'Image (Message.Crc) & " )");
end Messages.Queue.Debug;
```

Program Structure Lab Solution - CRC

```
private function Messages.Crc (Content : Content_T)
                                  return Crc_T;

function Messages.Crc (Content : Content_T)
                        return Crc_T is
   Ret_Val : Crc_T := 1;
begin
   for C of Content
   loop
      Ret_Val := Ret_Val * Character'Pos (C);
   end loop;
   return Ret_Val;
end Messages.Crc;
```

Program Structure Lab Solution - Main

```
with Ada.Text_IO; use Ada.Text_IO;
with Messages;
with Messages.Queue;
with Messages.Queue.Debug;
procedure Main is
   Char    : Character := 'A';
   Content : String (1 .. 10);
   Message : Messages.Message_T;
   Valid   : Boolean;
begin
   while not Messages.Queue.Full loop
      Content := (others => Char);
      Messages.Queue.Push (Messages.Create (Kind    => Messages.Command,
                                            Content => Content));
      Char := Character'Succ (Char);
   end loop;

   -- inject some faults
   Messages.Queue.Debug.Inject_Crc_Fault (3);
   Messages.Queue.Debug.Inject_Crc_Fault (6);

   while not Messages.Queue.Empty loop
      Put (Integer'Image (Messages.Queue.Debug.Queue_Length) & ") ");
      Messages.Queue.Pop (Message, Valid);
      Put_Line (Boolean'Image (Valid) & " " & Messages.Queue.Debug.Text (Message));
   end loop;

end Main;
```

Summary

Summary

- Hierarchical library units address important issues
  - Direct support for subsystems
  - Extension without recompilation
  - Separation of concerns with controlled sharing of visibility (Ada 2012)
- Parents should document assumptions for children
  - "These must always be in ascending order!"
- Children cannot misbehave unless imported ("with'ed")
- The writer of a child unit must be trusted
  - As much as if he or she were to modify the parent itself

Visibility

Introduction

Improving Readability

- Descriptive names plus hierarchical packages makes for very long statements

```
Messages.Queue.Diagnostics.Inject_Fault (
   Fault    => Messages.Queue.Diagnostics.CRC_Failure,
   Position => Messages.Queue.Front );
```

- Operators treated as functions defeat the purpose of overloading

```
Complex1 := Complex_Types."+" ( Complex2, Complex3 );
```

- Ada has mechanisms to simplify hierarchies

Operators and Primitives

- *Operators*
  - Constructs which behave generally like functions but which differ syntactically or semantically.
  - Typically arithmetic, comparison, and logical
- **Primitive operation**
  - Predefined operations such as = and + etc.
  - Subprograms declared in the same package as the type and which operate on the type
  - Inherited or overridden subprograms
  - For `tagged` types, class-wide subprograms
  - Enumeration literals

"use" Clauses

Examples

```
package Pkg_A is
   Constant_A  : constant := 1;
   Constant_Aa : constant := 11;
   Initialized : Boolean  := False;
end Pkg_A;

package Pkg_B is
   Constant_B  : constant := 20;
   Constant_Bb : constant := 220;
   Initialized : Boolean  := False;
end Pkg_B;

package Pkg_B.Child is
   Constant_Bbb : constant := 222;
end Pkg_B.Child;

with Pkg_A; use Pkg_A;
with Pkg_B;
with Pkg_B.Child;
package P is
   type Type_1 is range Constant_A .. -- visible without dot-notation
                        Pkg_B.Constant_B; -- not visible without dot-notation

   use Pkg_B;
   -- Constant_B is now visible without dot-notation
   type Type_2 is range Constant_Aa .. Constant_Bb;

   Constant_Bb : Integer := 33; -- Constant_Bb will always be the local version
   function Bb return Integer is (Constant_Bb);

   function Is_Initialized return Boolean is
     (Pkg_A.Initialized and Pkg_B.Initialized); -- Dot-notation to resolve ambiguity

   -- we "use" Pkg_B, so Child is directly visible
   Object : Integer := Child.Constant_Bbb;
end P;

with Ada.Text_IO; use Ada.Text_IO;
with P;
procedure Test is
   A, B, C : P.Type_2 := P.Type_2'First;
begin
   -- C := A + B; -- illegal
   C := P."+" (A, B); -- legal but not pretty
   Put_Line (C'Image);
   declare
      use P; -- make everything visible (including operators)
   begin
      C := A + B; -- now legal
      Put_Line (C'Image);
   end;
end Test;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/13S_visibility.html#use-clauses

use Clauses

- Provide direct visibility into packages' exported items
  - *Direct Visibility* - as if object was referenced from within package being used
- May still use expanded name

```
package Ada.Text_IO is
  procedure Put_Line( ... );
  procedure New_Line( ... );
  ...
end Ada.Text_IO;

with Ada.Text_IO;
procedure Hello is
  use Ada.Text_IO;
begin
  Put_Line( "Hello World" );
  New_Line(3);
  Ada.Text_IO.Put_Line ( "Good bye" );
end Hello;
```

use Clause Syntax

- May have several, like `with` clauses
- Can refer to any visible package (including nested packages)
- Syntax

```
use_package_clause ::= use package_name {, package_name}
```

- Can only `use` a package
  - Subprograms have no contents to `use`

use Clause Scope

- Applies to end of body, from first occurrence

```
package Pkg_A is
   Constant_A : constant := 123;
end Pkg_A;

package Pkg_B is
   Constant_B : constant := 987;
end Pkg_B;

with Pkg_A;
with Pkg_B;
use Pkg_A; -- everything in Pkg_A is now visible
package P is
   A  : Integer := Constant_A; -- legal
   B1 : Integer := Constant_B; -- illegal
   use Pkg_B; -- everything in Pkg_B is now visible
   B2 : Integer := Constant_B; -- legal
   function F return Integer;
end P;

package body P is
  -- all of Pkg_A and Pkg_B is visible here
  function F return Integer is ( Constant_A + Constant_B );
end P;
```

No Meaning Changes

- A new **use** clause won't change a program's meaning!
- Any directly visible names still refer to the original entities

```
package D is
  T : Real;
end D;

with D;
procedure P is
  procedure Q is
    T, X : Real;
  begin
    ...
    declare
      use D;
    begin
      -- With or without the clause, "T" means Q.T
      X := T;
    end;
    ...
  end Q;
```

No Ambiguity Introduction

```
package D is
  V : Boolean;
end D;

package E is
  V : Integer;
end E;
with D, E;

procedure P is
  procedure Q is
    use D, E;
  begin
    -- to use V here, must specify D.V or E.V
    ...
  end Q;
begin
...
```

use Clauses and Child Units

- A clause for a child does **not** imply one for its parent
- A clause for a parent makes the child **directly** visible
  - Since children are 'inside' declarative region of parent

```
package Parent is
  P1 : Integer;
end Parent;

package Parent.Child is
  PC1 : Integer;
end Parent.Child;

with Parent.Child;
procedure Demo is
  D1 : Integer := Parent.P1;
  D2 : Integer := Parent.Child.PC1;
  use Parent;
  D3 : Integer := P1;
  D4 : Integer := Child.PC1;
  ...
```

use Clause and Implicit Declarations

- Visibility rules apply to implicit declarations too

```
package P is
  type Int is range Lower .. Upper;
  -- implicit declarations
  -- function "+"( Left, Right : Int ) return Int;
  -- function "="( Left, Right : Int ) return Boolean;
end P;

with P;
procedure Test is
  A, B, C : P.Int := some_value;
begin
  C := A + B; -- illegal reference to operator
  C:= P."+" (A,B);
  declare
    use P;
  begin
    C := A + B; -- now legal
  end;
end Test;
```

"use type" Clauses

Examples

```
package P is
   type Int1 is range 0 .. 1_000;
   type Int2 is range 0 .. 2_000;
   type Int3 is range 0 .. 3_000;
   function "+" (Left  : Int1; Right : Int3) return Int3;
   function "+" (Left  : Int2; Right : Int3) return Int3;
end P;

with Ada.Text_IO; use Ada.Text_IO;
with P;
procedure Test is
   A, B, C : P.Int1 := 123;
   use type P.Int1;
   -- D : Int2; -- "Int2" is not visible
   D : P.Int2 := 234;
   E : P.Int3 := 345;
begin
   B := A;
   C := A + B; -- implicit operator is visible
   Put_Line (C'Image);
   A := B;
   E := A + E; -- "used" operator visible
   Put_Line (E'Image);
   -- E := D + E; -- illegal: operator not "used"
   -- E := E + A; -- illegal: no matching operator
end Test;

package body P is
   function "+" (Left  : Int1; Right : Int3) return Int3 is (Int3'Last);
   function "+" (Left  : Int2; Right : Int3) return Int3 is (Int3'Last);
end P;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/135_visibility.html#use-type-clauses

use type Clauses

- Syntax

```
use_type_clause ::= use type subtype_mark
                                    {, subtype_mark};
```

- Makes operators directly visible for specified type
  - Implicit and explicit operator function declarations
  - Only those that mention the type in the profile
    - Parameters and/or result type
- More specific alternative to `use` clauses
  - Especially useful when multiple `use` clauses introduce ambiguity

use type Clause Example

```
package P is
   type Int is range Lower .. Upper;
   -- implicit declarations
   -- function "+"( Left, Right : Int ) return Int;
   -- function "="( Left, Right : Int ) return Boolean;
end P;
with P;
procedure Test is
   A, B, C : P.Int := some_value;
   use type P.Int;
   D : Int; -- not legal
begin
   C := A + B; -- operator is visible
end Test;
```

use Type Clauses and Multiple Types

- One clause can make ops for several types visible
  - When multiple types are in the profiles
- No need for multiple clauses in that case

```
package P is
   type Miles_T is digits 6;
   type Hours_T is digits 6;
   type Speed_T is digits 6;
   -- "use type" on any of Miles_T, Hours_T, Speed_T
   -- makes operator visible
   function "/"( Left : Miles_T;
                 Right : Hours_T )
                 return Speed_T;
end P;
```

Multiple **use type** Clauses

- May be necessary
- Only those that mention the type in their profile are made visible

```
package P is
  type T1 is range 1 .. 10;
  type T2 is range 1 .. 10;
  -- implicit
  -- function "+"( Left : T2; Right : T2 ) return T2;
  type T3 is range 1 .. 10;
  -- explicit
  function "+"( Left : T1; Right : T2 ) return T3;
end P;

with P;
procedure UseType is
  X1 : P.T1;
  X2 : P.T2;
  X3 : P.T3;
  use type P.T1;
begin
  X3 := X1 + X2; -- operator visible because it uses T1
  X2 := X2 + X2; -- operator not visible
end UseType;
```

"use all type" Clauses

Examples

```
package Complex is
   type Number is private;
   function "*" (Left, Right : Number) return Number;
   function "+" (Left, Right : Number) return Number;
   procedure Put (C : Number);
   function Make (Real_Part, Imaginary_Part : Float) return Number;
   procedure Non_Primitive (X : Integer);
private
   type Number is record
      Real_Part      : Float;
      Imaginary_Part : Float;
   end record;
end Complex;

with Complex;
use all type Complex.Number;
procedure Demo_Use_All_Type is
   A, B, C : Complex.Number;
begin
   -- "use all type" makes these available
   A := Make (Real_Part      => 1.0,
              Imaginary_Part => 0.0);
   B := Make (Real_Part      => 1.0,
              Imaginary_Part => 0.0);
   C := A + B;
   Put (C);
   -- Non_Primitive (0); -- but not this one
end Demo_Use_All_Type;

with Complex;
use type Complex.Number;
procedure Demo_Use_Type is
   A, B, C : Complex.Number;
begin
   -- "use type" makes this available
   C := A + B;
   -- but not these
   -- A := Make (Real_Part      => 1.0,
   --            Imaginary_Part => 0.0);
   -- B := Make (Real_Part      => 1.0,
   --            Imaginary_Part => 0.0);
   -- Put (C);
   -- Non_Primitive (0);
end Demo_Use_Type;

with Complex; use Complex;
procedure Demo_Use is
   A, B, C : Complex.Number := (Complex.Make (1.1, 2.2));
begin
   -- "use" makes all these available
   C := A + B;
   A := Make (Real_Part      => 1.0,
              Imaginary_Part => 0.0);
   B := Make (Real_Part      => 1.0,
              Imaginary_Part => 0.0);
   Put (C);
   Non_Primitive (0);
end Demo_Use;

package body Complex is
   function "*" (Left, Right : Number) return Number is (Left);
   function "+" (Left, Right : Number) return Number is (Left);
   procedure Put (C : Number) is null;
   function Make (Real_Part, Imaginary_Part : Float) return Number is
     ((Real_Part, Imaginary_Part));
   procedure Non_Primitive (X : Integer) is null;
end Complex;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/E35_visibility.html#use-all-type-clauses

use all type Clauses

Ada 2012

- Makes all primitive operations for the type visible
  - Not just operators
  - Especially, subprograms that are not operators
- Still need a `use` clause for other entities
  - Typically exceptions

use all type Clause Example

Ada 2012

```
package Complex is
  type Number is private;
  function "+" (Left, Right : Number) return Number;
  procedure Make ( C : out Number;
                   From_Real, From_Imag : Float );
...
```

```
with Complex;
use all type Complex.Number;
procedure Demo is
  A, B, C : Complex.Number;
  procedure Non_Primitive ( X : Complex.Number ) is null;
begin
  -- "use all type" makes these available
  Make (A, From_Real => 1.0, From_Imag => 0.0);
  Make (B, From_Real => 1.0, From_Imag => 0.0);
  C := A + B;
  -- but not this one
  Non_Primitive (0);
end Demo;
```

use all type v. use type Example

Ada 2012

```
with Complex;   use type Complex.Number;
procedure Demo is
  A, B, C : Complex.Number;
Begin
  -- these are always allowed
  Complex.Make (A, From_Real => 1.0, From_Imag => 0.0);
  Complex.Make (B, From_Real => 1.0, From_Imag => 0.0);
  -- "use type" does not give access to these
  Make (A, 1.0, 0.0); -- not visible
  Make (B, 1.0, 0.0); -- not visible
  -- but this is good
  C := A + B;
  Complex.Put (C);
  -- this is not allowed
  Put (C); -- not visible
end Demo;
```

Renaming Entities

Three Positives Make a Negative

- Good Coding Practices ...
  - Descriptive names
  - Modularization
  - Subsystem hierarchies
- Can result in cumbersome references

```
-- use cosine rule to determine distance between two points,
-- given angle and distances between observer and 2 points
-- A**2 = B**2 + C**2 - 2*B*C*cos(A)
Observation.Sides (Viewpoint_Types.Point1_Point2) :=
  Math_Utilities.Square_Root
    (Observation.Sides (Viewpoint_Types.Observer_Point1)**2 +
     Observation.Sides (Viewpoint_Types.Observer_Point2)**2 +
     2.0 * Observation.Sides (Viewpoint_Types.Observer_Point1) *
       Observation.Sides (Viewpoint_Types.Observer_Point2) *
       Math_Utilities.Trigonometry.Cosine
         (Observation.Vertices (Viewpoint_Types.Observer)));
```

Writing Readable Code - Part 1

- We could use **use** on package names to remove some dot-notation

```
-- use cosine rule to determine distance between two points, given angle
-- and distances between observer and 2 points A**2 = B**2 + C**2 -
-- 2*B*C*cos(A)
Observation.Sides (Point1_Point2) :=
  Square_Root
    (Observation.Sides (Observer_Point1)**2 +
     Observation.Sides (Observer_Point2)**2 +
     2.0 * Observation.Sides (Observer_Point1) *
       Observation.Sides (Observer_Point2) *
       Cosine (Observation.Vertices (Observer)));
```

- But that only shortens the problem, not simplifies it
  - If there are multiple "use" clauses in scope:
    - Reviewer may have hard time finding the correct definition
    - Homographs may cause ambiguous reference errors
- We want the ability to refer to certain entities by another name (like an alias) with full read/write access (unlike temporary variables)

The **renames** Keyword

- Certain entities can be renamed within a declarative region
  - Packages

```
package Trig renames Math.Trigonometry
```

  - Objects (or elements of objects)

```
Angles : Viewpoint_Types.Vertices_Array_T
         renames Observation.Vertices;
Required_Angle : Viewpoint_Types.Vertices_T
         renames Viewpoint_Types.Observer;
```

  - Subprograms

```
function Sqrt (X : Base_Types.Float_T)
               return Base_Types.Float_T
               renames Math.Square_Root;
```

Writing Readable Code - Part 2

- With **renames** our complicated code example is easier to understand

```
begin
   package Math renames Math_Utilities;
   package Trig renames Math.Trigonometry;

   function Sqrt (X : Base_Types.Float_T) return Base_Types.Float_T
     renames Math.Square_Root;

   Side1          : Base_Types.Float_T
     renames Observation.Sides (Viewpoint_Types.Observer_Point1);
   -- Rename the others as Side2, Angles, Required_Angle, Desired_Side
begin
   ...
   -- use cosine rule to determine distance between two points, given angle
   -- and distances between observer and 2 points A**2 = B**2 + C**2 -
   -- 2*B*C*cos(A)
   Desired_Side :=
         Sqrt (Side1**2 + Side2**2 +
               2.0 * Side1 * Side2 * Trig.Cosine (Angles (Required_Angle)));
end;
```

Lab

Visibility Lab

- Requirements
  - Create a types package for calculating speed in miles per hour
    - At least two different distance measurements (e.g. feet, kilometers)
    - At least two different time measurements (e.g. seconds, minutes)
    - Overloaded operators and/or primitives to handle calculations
  - Create a types child package for converting distance, time, and mph into a string
    - Use `Ada.Text_IO.Float_IO` package to convert floating point to string
    - Create visible global objects to set **Exp** and **Aft** parameters for `Put`
  - Create a main program to enter distance and time and then print speed value
- Hints
  - `use` to get full visibility to **Ada.Text_IO**
  - `use type` to get access to calculations
    - `use all type` if calculations are primitives
  - `renames` to make using **Exp** and **Aft** easier

Visibility Lab Solution - Types

```
package Types is
   type Mph_T is digits 6;
   type Feet_T is digits 6;
   type Miles_T is digits 6;
   type Kilometers_T is digits 6;
   type Seconds_T is digits 6;
   type Minutes_T is digits 6;
   type Hours_T is digits 6;

   function "/" (Distance : Feet_T; Time : Seconds_T) return Mph_T;
   function "/" (Distance : Kilometers_T; Time : Minutes_T) return Mph_T;
   function "/" (Distance : Miles_T; Time : Hours_T) return Mph_T;

   function Convert (Distance : Feet_T) return Miles_T;
   function Convert (Distance : Kilometers_T) return Miles_T;
   function Convert (Time : Seconds_T) return Hours_T;
   function Convert (Time : Minutes_T) return Hours_T;
end Types;

package body Types is
   function "/" (Distance : Feet_T; Time : Seconds_T) return Mph_T is (Convert (Distance) / Convert (Time));
   function "/" (Distance : Kilometers_T; Time : Minutes_T) return Mph_T is (Convert (Distance) / Convert (Time));
   function "/" (Distance : Miles_T; Time : Hours_T) return Mph_T is (Mph_T (Distance) / Mph_T (Time));

   function Convert (Distance : Feet_T) return Miles_T is (Miles_T (Distance) / 5_280.0);
   function Convert (Distance : Kilometers_T) return Miles_T is (Miles_T (Distance) / 1.6);

   function Convert (Time : Seconds_T) return Hours_T is (Hours_T (Time) / (60.0 * 60.0));
   function Convert (Time : Minutes_T) return Hours_T is (Hours_T (Time) / 60.0);
end Types;
```

Visibility Lab Solution - Types.Strings

```
package Types.Strings is
   Exponent_Digits      : Natural := 2;
   Digits_After_Decimal : Natural := 3;

   function To_String (Value : Mph_T) return String;
   function To_String (Value : Feet_T) return String;
   function To_String (Value : Miles_T) return String;
   function To_String (Value : Kilometers_T) return String;
   function To_String (Value : Seconds_T) return String;
   function To_String (Value : Minutes_T) return String;
   function To_String (Value : Hours_T) return String;
end Types.Strings;
```

```
with Ada.Text_IO; use Ada.Text_IO;
package body Types.Strings is
   package Io is new Ada.Text_IO.Float_IO (Float);
   function To_String (Value : Float) return String is
      Ret_Val : String (1 .. 30);
   begin
      Io.Put (To   => Ret_Val,
              Item => Value,
              Aft  => Digits_After_Decimal,
              Exp  => Exponent_Digits);
      for I in reverse Ret_Val'Range loop
         if Ret_Val (I) = ' ' then
            return Ret_Val (I + 1 .. Ret_Val'Last);
         end if;
      end loop;
      return Ret_Val;
   end To_String;

   function To_String (Value : Mph_T) return String is (To_String (Float (Value)));
   function To_String (Value : Feet_T) return String is (To_String (Float (Value)));
   function To_String (Value : Miles_T) return String is (To_String (Float (Value)));
   function To_String (Value : Kilometers_T) return String is (To_String (Float (Value)));
   function To_String (Value : Seconds_T) return String is (To_String (Float (Value)));
   function To_String (Value : Minutes_T) return String is (To_String (Float (Value)));
   function To_String (Value : Hours_T) return String is (To_String (Float (Value)));
end Types.Strings;
```

Visibility Lab Solution - Main

```
with Ada.Text_IO; use Ada.Text_IO;
with Types;       use Types;
with Types.Strings;
procedure Main is
   Aft : Integer renames Types.Strings.Digits_After_Decimal;
   Exp : Integer renames Types.Strings.Exponent_Digits;

   Feet       : Feet_T;
   Miles      : Miles_T;
   Kilometers : Kilometers_T;
   Seconds    : Seconds_T;
   Minutes    : Minutes_T;
   Hours      : Hours_T;
   Mph        : Mph_T;

   function Get (Prompt : String) return String is
   begin
      Put (Prompt & "> ");
      return Get_Line;
   end Get;

begin
   Feet       := Feet_T'Value (Get ("Feet"));
   Miles      := Miles_T'Value (Get ("Miles"));
   Kilometers := Kilometers_T'Value (Get ("Kilometers"));

   Seconds := Seconds_T'Value (Get ("Seconds"));
   Minutes := Minutes_T'Value (Get ("Minutes"));
   Hours   := Hours_T'Value (Get ("Hours"));

   Aft := 2;
   Exp := 2;
   Mph := Feet / Seconds;
   Put_Line (Strings.To_String (Feet) & " feet / " & Strings.To_String (Seconds) &
             " seconds = " & Strings.To_String (Mph) & " mph");
   Aft := Aft + 1;
   Exp := Exp + 1;
   Mph := Miles / Hours;
   Put_Line (Strings.To_String (Miles) & " miles / " & Strings.To_String (Hours) &
             " hour = " & Strings.To_String (Mph) & " mph");
   Aft := Aft + 1;
   Exp := Exp + 1;
   Mph := Kilometers / Minutes;
   Put_Line (Strings.To_String (Kilometers) & " km / " & Strings.To_String (Minutes) &
             " minute = " & Strings.To_String (Mph) & " mph");
end Main;
```

Summary

Summary

Ada 2012

- `use` clauses are not evil but can be abused
  - Can make it difficult for others to understand code
- `use all type` clauses are more likely in practice than `use type` clauses
  - Only available in Ada 2012 and later
- `Renames` allow us to alias entities to make code easier to read
  - Subprogram renaming has many other uses, such as adding / removing default parameter values

Tagged Derivation

Introduction

Object-Oriented Programming With Tagged Types

- For `record` types

```
type T is tagged record
...
```

- Child types can add new components (*attributes*)
- Object of a child type can be **substituted** for base type
- Primitive (*method*) can *dispatch* **at runtime** depending on the type at call-site
- Types can be **extended** by other packages
  - Casting and qualification to base type is allowed
- Private data is encapsulated through **privacy**

Tagged Derivation Ada vs C++

```
type T1 is tagged record
  Member1 : Integer;
end record;

procedure Attr_F (This : T1);

type T2 is new T1 with record
  Member2 : Integer;
end record;

overriding procedure Attr_F (
     This : T2);
procedure Attr_F2 (This : T2);
```

```
class T1 {
  public:
    int Member1;
    virtual void Attr_F(void);
  };

class T2 : public T1 {
  public:
    int Member2;
    virtual void Attr_F(void);
    virtual void Attr_F2(void)
  };
```

Tagged Derivation

Examples

```
package Tagged_Derivation is

   type Root_T is tagged record
      Root_Field : Integer;
   end record;
   function Primitive_1 (This : Root_T) return Integer is (This.Root_Field);
   function Primitive_2 (This : Root_T) return String is
     (Integer'Image (This.Root_Field));

   type Child_T is new Root_T with record
      Child_Field : Integer;
   end record;
   overriding function Primitive_2 (This : Child_T) return String is
     (Integer'Image (This.Root_Field) & " " &
      Integer'Image (This.Child_Field));
   function Primitive_3 (This : Child_T) return Integer is
     (This.Root_Field + This.Child_Field);

   -- type Simple_Deriviation_T is new Child_T; -- illegal

   type Root2_T is tagged record
      Root_Field : Integer;
   end record;
   -- procedure Primitive_4 (X : Root_T; Y : Root2_T); -- illegal

end Tagged_Derivation;

with Ada.Text_IO;       use Ada.Text_IO;
with Tagged_Derivation; use Tagged_Derivation;
procedure Test_Tagged_Derivation is
   Root  : Root_T  := (Root_Field => 1);
   Child : Child_T := (Root_Field => 11, Child_Field => 22);
begin
   Put_Line ("Root: " & Primitive_2 (Root));
   Put_Line ("Child: " & Primitive_2 (Child));
   Root := Root_T (Child);
   Put_Line ("Root from Child: " & Primitive_2 (Root));
   -- Child := Child_T ( Root ); -- illegal
   -- Put_Line ( "Child from Root: " & Primitive_2 ( Child ) ); -- illegal
   Child := (Root with Child_Field => 999);
   Put_Line ("Child from Root via aggregate: " & Primitive_2 (Child));
end Test_Tagged_Derivation;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/170_tagged_derivation.html#tagged-derivation

Difference with Simple Derivation

- Tagged derivation **can** change the structure of a type
  - Keywords `tagged record` and `with record`

```
type Root is tagged record
   F1 : Integer;
end record;

type Child is new Root with record
   F2 : Integer;
end record;
```

Type Extension

- A tagged derivation **has** to be a type extension
  - Use `with null record` if there are no additional components

```
type Child is new Root with null record;
type Child is new Root; -- illegal
```

- Conversions is only allowed from **child to parent**

```
V1 : Root;
V2 : Child;
...
V1 := Root (V2);
V2 := Child (V1); -- illegal
```

Primitives

- Child **cannot remove** a primitive
- Child **can add** new primitives
- *Controlling parameter*
  - Parameters the subprogram is a primitive of
  - For `tagged` types, all should have the **same type**

```
type Root1 is tagged null record;
type Root2 is tagged null record;

procedure P1 (V1 : Root1;
              V2 : Root1);
procedure P2 (V1 : Root1;
              V2 : Root2); -- illegal
```

Freeze Point For Tagged Types

- Freeze point definition does not change
  - A variable of the type is declared
  - The type is derived
  - The end of the scope is reached
- Declaring tagged type primitives past freeze point is **forbidden**

```
type Root is tagged null record;

procedure Prim (V : Root);

type Child is new Root with null record; -- freeze root

procedure Prim2 (V : Root); -- illegal

V : Child; --  freeze child

procedure Prim3 (V : Child); -- illegal
```

Tagged Aggregate

- At initialization, all fields (including **inherited**) must have a **value**

```
type Root is tagged record
    F1 : Integer;
end record;

type Child is new Root with record
    F2 : Integer;
end record;

V : Child := (F1 => 0, F2 => 0);
```

- For **private types** use *aggregate extension*
  - Copy of a parent instance
  - Use `with null record` absent new fields

```
V2 : Child := (Parent_Instance with F2 => 0);
V3 : Empty_Child := (Parent_Instance with null record);
```

Overriding Indicators

Ada 2005

- Optional `overriding` and `not overriding` indicators

```
type Shape_T is tagged record
   Name : String(1..10);
end record;

-- primitives of "Shape_T"
procedure Set_Name (S : in out Shape_T);
function Name (S : Shape_T) return string;

-- Derive "Point" from Shape_T
type Point is new Shape_T with record
   Origin : Coord_T;
end Point;

-- We want to _change_ the behavior of Set_Name
overriding procedure Set_Name (P : in out Point_T);
-- We want to _add_ a new primitive
not overriding Origin ( P : Point_T ) return Point_T;
-- We get "Name" for free
```

Prefix Notation

Ada 2012

- Tagged types primitives can be called as usual
- The call can use prefixed notation
  - **If** the first argument is a controlling parameter
  - No need for `use` or `use type` for visibility

```
-- Prim1 visible even without *use Pkg*
X.Prim1;

declare
   use Pkg;
begin
   Prim1 (X);
end;
```

Quiz

Which declaration(s) will make `P` a primitive of `T1`?

A.
```
type T1 is tagged null record;
procedure P (O : T1) is null;
```

B.
```
type T0 is tagged null record;
type T1 is new T0 with null record;
type T2 is new T0 with null record;
procedure P (O : T1) is null;
```

C.
```
type T1 is tagged null record;
generic
  type T is tagged private;
package G_Pkg is
  type T2 is new T with null record;
end G_Pkg;
package Pkg is new G_Pkg (T1);
procedure P (O : T1) is null;
```

D.
```
type T1 is tagged null record;
generic
  type T;
procedure G_P (O : T);
procedure G_P (O : T) is null;
procedure P is new G_P (T1);
```

Quiz

Which declaration(s) will make `P` a primitive of `T1`?

A.
```
type T1 is tagged null record;
procedure P (O : T1) is null;
```

B.
```
type T0 is tagged null record;
type T1 is new T0 with null record;
type T2 is new T0 with null record;
procedure P (O : T1) is null;
```

C.
```
type T1 is tagged null record;
generic
  type T is tagged private;
package G_Pkg is
  type T2 is new T with null record;
end G_Pkg;
package Pkg is new G_Pkg (T1);
procedure P (O : T1) is null;
```

D.
```
type T1 is tagged null record;
generic
  type T;
procedure G_P (O : T);
procedure G_P (O : T) is null;
procedure P is new G_P (T1);
```

Quiz

```
with Pkg1; -- Defines tagged type Tag1, with primitive P
with Pkg2; use Pkg2; -- Defines tagged type Tag2, with primitive P
with Pkg3; -- Defines tagged type Tag3, with primitive P
use type Pkg3.Tag3;

procedure Main is
   O1 : Pkg1.Tag1;
   O2 : Pkg2.Tag2;
   O3 : Pkg3.Tag3;
```

Which statement(s) is(are) valid?

A. `O1.P`
B. `P (O1)`
C. `P (O2)`
D. `P (O3)`

Quiz

```
with Pkg1; -- Defines tagged type Tag1, with primitive P
with Pkg2; use Pkg2; -- Defines tagged type Tag2, with primitive P
with Pkg3; -- Defines tagged type Tag3, with primitive P
use type Pkg3.Tag3;

procedure Main is
   O1 : Pkg1.Tag1;
   O2 : Pkg2.Tag2;
   O3 : Pkg3.Tag3;
```

Which statement(s) is(are) valid?

A. *O1.P*
B. P (O1)
C. *P (O2)*
D. P (O3)

D. Only operators are `use`d, should have been :ada:`use all`

Quiz

Which code block is legal?

A.
```
type A1 is record
  Field1 : Integer;
end record;
type A2 is new A1 with
null record;
```

B.
```
type B1 is tagged
record
  Field2 :  Integer;
end record;
type B2 is new B1 with
record
  Field2b :  Integer;
end record;
```

C.
```
type C1 is tagged
record
  Field3 : Integer;
end record;
type C2 is new C1 with
record
  Field3 : Integer;
end record;
```

D.
```
type D1 is tagged
record
  Field1 : Integer;
end record;
type D2 is new D1;
```

Quiz

Which code block is legal?

A.
```
type A1 is record
  Field1 : Integer;
end record;
type A2 is new A1 with
null record;
```

B.
```
type B1 is tagged
record
  Field2 :  Integer;
end record;
type B2 is new B1 with
record
  Field2b :  Integer;
end record;
```

C.
```
type C1 is tagged
record
  Field3 : Integer;
end record;
type C2 is new C1 with
record
  Field3 : Integer;
end record;
```

D.
```
type D1 is tagged
record
  Field1 : Integer;
end record;
type D2 is new D1;
```

Explanations

A. Cannot extend a non-tagged type
B. Correct
C. Components must have distinct names
D. Types derived from a tagged type must have an extension

Lab

Tagged Derivation Lab

- Requirements
  - Create a type structure that could be used in a business
    - A **person** has some defining characteristics
    - An **employee** is a *person* with some employment information
    - A **staff member** is an *employee* with specific job information
  - Create primitive operations to read and print the objects
  - Create a main program to test the objects and operations
- Hints
  - Use **overriding** and **not overriding** as appropriate

Tagged Derivation Lab Solution - Types (Spec)

```
with Ada.Calendar;
with Ada.Strings.Unbounded; use Ada.Strings.Unbounded;
package Employee is
  type Person_T is tagged private;
  procedure Set_Name (O     : in out Person_T;
                      Value :        String);
  function Name (O : Person_T) return String;
  procedure Set_Birth_Date (O     : in out Person_T;
                            Value :        String);
  function Birth_Date (O : Person_T) return String;
  procedure Print (O : Person_T);

  type Employee_T is new Person_T with private;
  not overriding procedure Set_Start_Date (O     : in out Employee_T;
                                           Value :        String);
  not overriding function Start_Date (O : Employee_T) return String;
  overriding procedure Print (O : Employee_T);

  type Position_T is new Employee_T with private;
  not overriding procedure Set_Job (O     : in out Position_T;
                                    Value :        String);
  not overriding function Job (O : Position_T) return String;
  overriding procedure Print (O : Position_T);

private
  type Person_T is tagged record
    Name       : Unbounded_String;
    Birth_Date : Ada.Calendar.Time;
  end record;

  type Employee_T is new Person_T with record
    Employee_Id : Positive;
    Start_Date  : Ada.Calendar.Time;
  end record;

  type Position_T is new Employee_T with record
    Job : Unbounded_String;
  end record;
end Employee;
```

Tagged Derivation Lab Solution - Types (Body - Incomplete)

```
function To_String (T : Ada.Calendar.Time) return String is
begin
  return Month_Name (Ada.Calendar.Month (T)) &
   Integer'Image (Ada.Calendar.Day (T)) & "," &
   Integer'Image (Ada.Calendar.Year (T));
end To_String;

function From_String (S : String) return Ada.Calendar.Time is
  Date : constant String := S & " 12:00:00";
begin
  return Ada.Calendar.Formatting.Value (Date);
end From_String;

procedure Set_Name (O     : in out Person_T;
                    Value :        String) is
begin
  O.Name := To_Unbounded_String (Value);
end Set_Name;
function Name (O : Person_T) return String is (To_String (O.Name));

  Put_Line ("Birthdate: " & Birth_Date (O));
end Print;

not overriding procedure Set_Start_Date (O     : in out Employee_T;
                                         Value :        String) is
begin
  O.Start_Date := From_String (Value);
end Set_Start_Date;
not overriding function Start_Date (O : Employee_T) return String is (To_String (O.Start_Date));
overriding procedure Print (O : Employee_T) is
begin
  Put_Line ("Name: " & Name (O));
  Put_Line ("Birthdate: " & Birth_Date (O));
  Put_Line ("Startdate: " & Start_Date (O));
end Print;
```

Tagged Derivation Lab Solution - Main

```
with Ada.Text_IO; use Ada.Text_IO;
with Employee;
procedure Main is
  function Read (Prompt : String) return String is
  begin
    Put (Prompt & "> ");
    return Get_Line;
  end Read;
  function Read_Date (Prompt : String) return String is (Read (Prompt & " (YYYY-MM-DD)"));

  Applicant : Employee.Person_T;
  Employ    : Employee.Employee_T;
  Staff     : Employee.Position_T;

begin
  Applicant.Set_Name (Read ("Applicant name"));
  Applicant.Set_Birth_Date (Read_Date ("   Birth Date"));

  Employ.Set_Name (Read ("Employee name"));
  Employ.Set_Birth_Date (Read_Date ("   Birth Date"));
  Employ.Set_Start_Date (Read_Date ("   Start Date"));

  Staff.Set_Name (Read ("Staff name"));
  Staff.Set_Birth_Date (Read_Date ("   Birth Date"));
  Staff.Set_Start_Date (Read_Date ("   Start Date"));
  Staff.Set_Job (Read ("   Job"));

  Applicant.Print;
  Employ.Print;
  Staff.Print;
end Main;
```

Summary

Summary

- Tagged derivation
  - Building block for OOP types in Ada
- Primitives rules for tagged types are trickier
  - Primitives **forbidden** below freeze point
  - **Unique** controlling parameter
  - Tip: Keep the number of tagged type per package low

Polymorphism

Introduction

Introduction

- `'Class` operator to categorize *classes of types*
- Type classes allow dispatching calls
  - Abstract types
  - Abstract subprograms
- Run-time call dispatch vs compile-time call dispatching

Classes of Types

Examples

```
package Class_Types is
   type Root_T is tagged null record;
   type Child1_T is new Root_T with null record;
   type Child2_T is new Root_T with null record;
   type Grandchild1_T is new Child1_T with null record;

   -- Root'Class = {Root_T, Child1_T, Child2_T, Grandchild1_T}
   -- Child1'Class = {Child1_T, Grandchild1_T} Child2'Class = {Child2_T}
   -- Grandchild1'Class ={Grandchild1_T}
   procedure Test;

end Class_Types;

with Ada.Tags;    use Ada.Tags;
with Ada.Text_IO; use Ada.Text_IO;
package body Class_Types is
   Root_Object  : Root_T;
   Child_Object : Child1_T;

   Class_Object1 : Child1_T'Class := Child_Object;
   Class_Object2 : Root_T'Class   := Class_Object1;
   Class_Object3 : Root_T'Class   := Child_Object;
   -- Class_Object4 : Root_T'class; -- illegal

   procedure Do_Something (Object : in out Root_T'Class) is
   begin
      Put_Line
        ("Do_Something: " & Boolean'Image (Object in Root_T'Class) & " / " &
          Boolean'Image (Object in Child1_T'Class));
   end Do_Something;

   procedure Test is
   begin
      Put_Line (Boolean'Image (Class_Object1'Tag = Class_Object2'Tag));
      Put_Line (Boolean'Image (Class_Object2'Tag = Class_Object3'Tag));
      Do_Something (Root_Object);
      Do_Something (Child_Object);
      Do_Something (Class_Object1);
      Do_Something (Class_Object2);
      Do_Something (Class_Object3);
   end Test;
end Class_Types;

package Abstract_Types is
   type Root_T is abstract tagged record
      Field : Integer;
   end record;
   function Primitive1 (V : Root_T) return String is abstract;
   function Primitive2 (Prompt : String; V : Root_T) return String is
      (Prompt & "> " & Integer'Image (V.Field));

   type Child_T is abstract new Root_T with null record;
   -- Child_T does not need to redefine any primitives

   type Grandchild_T is new Child_T with null record;
   -- Grandchild_T is required to create a concrete version of Primitive2
   function Primitive1 (V : Grandchild_T) return String is
     (Integer'Image (V.Field));

   procedure Test;
end Abstract_Types;

with Ada.Text_IO; use Ada.Text_IO;
package body Abstract_Types is
   Object1 : constant Grandchild_T := (Field => 123);
   Object2 : constant Root_T'Class := Object1;

   procedure Test is
   begin
      Put_Line (Object1.Primitive1);
      Put_Line (Primitive2 ("Object1", Object2));
      Put_Line (Object2.Primitive1);
      Put_Line (Primitive2 ("Object2", Object2));
   end Test;

end Abstract_Types;

with Abstract_Types;
with Class_Types;
procedure Test is
begin
   Class_Types.Test;
   Abstract_Types.Test;
end Test;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/182_polymorphism.html#classes-of-types

Classes

- In Ada, a Class denotes an inheritance subtree
- Class of **T** is the class of **T** and all its children
- Type `T'Class` can designate any object typed after type of class of **T**

```
type Root is tagged null record;
type Child1 is new Root with null record;
type Child2 is new Root with null record;
type Grand_Child1 is new Child1 with null record;
-- Root'Class = {Root, Child1, Child2, Grand_Child1}
-- Child1'Class = {Child1, Grand_Child1}
-- Child2'Class = {Child2}
-- Grand_Child1'Class = {Grand_Child1}
```

- Objects of type `T'Class` have at least the properties of T
  - Fields of **T**
  - Primitives of **T**

Indefinite type

- A class wide type is an indefinite type
  - Just like an unconstrained array or a record with a discriminant
- Properties and constraints of indefinite types apply
  - Can be used for parameter declarations
  - Can be used for variable declaration with initialization

```
procedure Main is
   type T is tagged null record;
   type D is new T with null record;
   procedure P (X : in out T'Class) is null;
   Obj : D;
   Dc  : D'Class := Obj;
   Tc1 : T'Class := Dc;
   Tc2 : T'Class := Obj;
   -- initialization required in class-wide declaration
   Tc3 : T'Class; -- compile error
   Dc2 : D'Class; -- compile error
begin
   P (Dc);
   P (Obj);
end Main;
```

Testing the type of an object

- The tag of an object denotes its type
- It can be accessed through the **'Tag** attribute
- Applies to both objects and types
- Membership operator is available to check the type against a hierarchy

```
type Parent is tagged null record;
type Child is new Parent with null record;
Parent_Obj : Parent; -- Parent_Obj'Tag = Parent'Tag
Child_Obj  : Child;  -- Child_Obj'Tag = Child'Tag
Parent_Class_1 : Parent'Class := Parent_Obj;
                 -- Parent_Class_1'Tag = Parent'Tag
Parent_Class_2 : Parent'Class := Child_Obj;
                 -- Parent_Class_2'Tag = Child'Tag
Child_Class    : Child'Class := Child(Parent_Class_2);
                 -- Child_Class'Tag  = Child'Tag

B1 : Boolean := Parent_Class_1 in Parent'Class;       -- True
B2 : Boolean := Parent_Class_1'Tag = Child'Tag; -- False
B3 : Boolean := Child_Class'Tag = Parent'Tag;   -- False
B4 : Boolean := Child_Class in Child'Class;           -- True
```

Abstract Types

- A tagged type can be declared `abstract`
- Then, `abstract tagged` types:
  - cannot be instantiated
  - can have abstract subprograms (with no implementation)
  - Non-abstract derivation of an abstract type must override and implement abstract subprograms

Abstract Types Ada vs C++

- Ada

```
type Root is abstract tagged record
   F : Integer;
end record;
procedure P1 (V : Root) is abstract;
procedure P2 (V : Root);
type Child is abstract new Root with null record;
type Grand_Child is new Child with null record;

overriding  -- Ada 2005 and later
procedure P1 (V : Grand_Child);
```

- C++

```
class Root {
   public:
      int F;
      virtual void P1 (void) = 0;
      virtual void P2 (void);
};
class Child : public Root {
};
class Grand_Child {
   public:
      virtual void P1 (void);
};
```

Relation to Primitives

Ada 2012

- Warning: Subprograms with parameter of type **T'Class** are not primitives of **T**

```
type Root is tagged null record;
procedure P (V : Root'Class);
type Child is new Root with null record;
-- This does not override P!
overriding procedure P (V : Child'Class);
```

- Prefix notation rules apply when the first parameter is of a class wide type

```
V1 : Root;
V2 : Root'Class := Root'(others => <>);
...
P (V1);
P (V2);
V1.P;
V2.P;
```

Dispatching and Redispatching

Examples

```
package Types is

   type Root_T is tagged null record;
   function Primitive (V : Root_T) return String is ("Root_T");

   type Child_T is new Root_T with null record;
   function Primitive (V : Child_T) return String is ("Child_T");

end Types;

with Ada.Text_IO; use Ada.Text_IO;
with Types;       use Types;
procedure Test_Dispatching_And_Redispatching is

   Root_Object  : Root_T;
   Child_Object : Child_T;

   V1 : constant Root_T'Class  := Root_Object;
   V2 : constant Root_T'Class  := Child_Object;
   V3 : constant Child_T'Class := Child_Object;

begin

   Put_Line (Primitive (V1));
   Put_Line (Primitive (V2));
   Put_Line (Primitive (V3));

end Test_Dispatching_And_Redispatching;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/180_polymorphism.html#dispatching-and-redispatching

Calls on class-wide types (1/3)

- Any subprogram expecting a T object can be called with a `T'Class` object

```
type Root is tagged null record;
procedure P (V : Root);

type Child is new Root with null record;
procedure P (V : Child);

   V1 : Root'Class := [...]
   V2 : Child'Class := [...]
begin
   P (V1);
   P (V2);
```

Calls on class-wide types (2/3)

- The *actual* type of the object is not known at compile time
- The *right* type will be selected at runtime

Ada

```
declare
   V1 : Root'Class :=
        Root'(others => <>);
   V2 : Root'Class :=
        Child'(others => <>);
begin
   V1.P; -- calls P of Root
   V2.P; -- calls P of Child
```

C++

```
Root * V1 = new Root ();
Root * V2 = new Child ();
V1->P ();
V2->P ();
```

Calls on class-wide types (3/3)

- It is still possible to force a call to be static using a conversion of view

Ada

```
declare
   V1 : Root'Class :=
        Root'(others => <>);
   V2 : Root'Class :=
        Child'(others => <>);
begin
   Root (V1).P; -- calls P of Root
   Root (V2).P; -- calls P of Root
```

C++

```
Root * V1 = new Root ();
Root * V2 = new Child ();
((Root) *V1).P ();
((Root) *V2).P ();
```

Definite and class wide views

- In C++, dispatching occurs only on pointers
- In Ada, dispatching occurs only on class wide views

```
type Root is tagged null record;
procedure P1 (V : Root);
procedure P2 (V : Root);
type Child is new Root with null record;
overriding procedure P2 (V : Child);
procedure P1 (V : Root) is
begin
   P2 (V); -- always calls P2 from Root
end P1;
procedure Main is
   V1 : Root'Class :=
        Child'(others => <>);
begin
   -- Calls P1 from the implicitly overridden subprogram
   -- Calls P2 from Root!
   V1.P1;
```

Redispatching

- `tagged` types are always passed by reference
  - The original object is not copied
- Therefore, it is possible to convert them to different views

```
type Root is tagged null record;
procedure P1 (V : Root);
procedure P2 (V : Root);
type Child is new Root with null record;
overriding procedure P2 (V : Child);
```

Redispatching Example

```
procedure P1 (V : Root) is
   V_Class : Root'Class renames
             Root'Class (V); -- naming of a view
begin
   P2 (V);                   -- static: uses the definite view
   P2 (Root'Class (V)); -- dynamic: (redispatching)
   P2 (V_Class);             -- dynamic: (redispatching)

   -- Ada 2005 "distinguished receiver" syntax
   V.P2;                     -- static: uses the definite view
   Root'Class (V).P2;   -- dynamic: (redispatching)
   V_Class.P2;               -- dynamic: (redispatching)
end P1;
```

Quiz

```
package P is
   type Root is tagged null record;
   function F1 (V : Root) return Integer is (101);
   type Child is new Root with null record;
   function F1 (V : Child) return Integer is (201);
   type Grandchild is new Child with null record;
   function F1 (V : Grandchild) return Integer is (301);
end P;

with P1; use P1;
procedure Main is
   Z : Root'Class := Grandchild'(others => <>);
```

What is the value returned by `F1 (Child'Class (Z));`?

A. 301
B. 201
C. 101
D. Compilation error

Quiz

```
package P is
   type Root is tagged null record;
   function F1 (V : Root) return Integer is (101);
   type Child is new Root with null record;
   function F1 (V : Child) return Integer is (201);
   type Grandchild is new Child with null record;
   function F1 (V : Grandchild) return Integer is (301);
end P;

with P1; use P1;
procedure Main is
   Z : Root'Class := Grandchild'(others => <>);
```

What is the value returned by `F1 (Child'Class (Z));`?

A. ***301***
B. 201
C. 101
D. Compilation error

Explanations

A. Correct
B. Would be correct if the cast was `Child` - `Child'Class` leaves the object as `Grandchild`
C. Object is initialized to something in `Root'class`, but it doesn't have to be `Root`
D. Would be correct if function parameter types were `'Class`

Exotic Dispatching Operations

Examples

```
package Types is
   type Root_T is tagged record
      Field : Integer;
   end record;
   function Primitive (Left  : Root_T; Right : Root_T) return Integer is
      (Left.Field + Right.Field);
   function "=" (Left  : Root_T; Right : Root_T) return Boolean is
      (Left.Field in Right.Field - 1 .. Right.Field + 1);
   function Constructor (I : Integer := 0) return Root_T is ((Field => I));

   type Child_T is new Root_T with null record;
   overriding function Primitive (Left  : Child_T; Right : Child_T) return Integer is
      (Left.Field * Right.Field);
   overriding function "=" (Left  : Child_T; Right : Child_T) return Boolean is
      (Right.Field in Left.Field - 1 .. Left.Field + 1);
   -- function Constructor ( I : Integer := 0 ) return child_T; -- inherited from Root_t

   type Child2_T is new Root_T with record
      Field2 : Integer;
   end record;
   overriding function Primitive (Left  : Child2_T; Right : Child2_T) return Integer is
      (Left.Field * Right.Field);
   overriding function "=" (Left  : Child2_T; Right : Child2_T) return Boolean is
      (Left.Field = Right.Field);
   -- must create a constructor because new fields added
   function Constructor (I : Integer := 0) return Child2_T is ((I, I));
end Types;

with Ada.Text_IO; use Ada.Text_IO;
with Types;       use Types;
procedure Test_Exotic_Dispatching_Operations is
   R1  : constant Root_T       := (Field => 10);
   R2  : constant Root_T       := (Field => 20);
   C1  : constant Child_T      := (Field => 10);

   procedure Test_Primitive is
   begin
      Put_Line ("Primitive");
      Put_Line (Integer'Image (Primitive (R1, R2)));                 -- static:  ok
      -- Put_Line (Integer'Image (Primitive (R1, C1)));              -- static: error
      Put_Line (Integer'Image (Primitive (C11, C12)));               -- dynamic: ok
      -- Put_Line (Integer'Image (Primitive (R1, C11)));             -- static: error
      Put_Line (Integer'Image (Primitive (Root_T'Class (R1), C1))); -- dynamic: ok
      Put_Line (Integer'Image (Primitive (C11, C13)));               -- dynamic: error
   end Test_Primitive;

   procedure Test_Equality is
   begin
      Put_Line ("Equality");
      Put_Line ("C11 = C12 " & Boolean'Image (C11 = C12));
      Put_Line ("C12 = C13 " & Boolean'Image (C12 = C13));
      Put_Line ("C13 = C11 " & Boolean'Image (C13 = C11));
   end Test_Equality;

   procedure Test_Constructor is
      -- Static call to Root_T primitive
      V1 : Root_T'Class := Root_T'(Constructor);
      V2 : Root_T'Class := V1;
      -- Static call to Child2_T primitive
      V3 : Root_T'Class := Child2_T'(Constructor);
      -- V4 : Root_T'Class := Constructor; -- What is the tag of V4?
   begin
      -- No
      -- V1 := Constructor;

      -- Yes
      V1 := Root_T'(Constructor);
   end Test_Constructor;

begin
   Test_Equality;
   Test_Constructor;
   Test_Primitive;
end Test_Exotic_Dispatching_Operations;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/180_polymorphism.html#exotic-dispatching-operations

Multiple dispatching operands

- Primitives with multiple dispatching operands are allowed if all operands are of the same type

```
type Root is tagged null record;
procedure P (Left : Root; Right : Root);
type Child is new Root with null record;
overriding procedure P (Left : Child; Right : Child);
```

- At call time, all actual parameters' tags have to match, either statically or dynamically

```
R1, R2 : Root;
C1, C2 : Child;
Cl1 : Root'Class := R1;
Cl2 : Root'Class := R2;
Cl3 : Root'Class := C1;
...
P (R1, R2);                -- static:  ok
P (R1, C1);                -- static:  error
P (Cl1, Cl2);              -- dynamic: ok
P (Cl1, Cl3);              -- dynamic: error
P (R1, Cl1);               -- static:  error
P (Root'Class (R1), Cl1); -- dynamic: ok
```

Special case for equality

- Overriding the default equality for a `tagged` type involves the use of a function with multiple controlling operands
- As in general case, static types of operands have to be the same
- If dynamic types differ, equality returns false instead of raising exception

```
type Root is tagged null record;
function "=" (L : Root; R : Root) return Boolean;
type Child is new Root with null record;
overriding function "=" (L : Child; R : Child) return Boolean;
R1, R2 : Root;
C1, C2 : Child;
Cl1 : Root'Class := R1;
Cl2 : Root'Class := R2;
Cl3 : Root'Class := C1;
...
-- overridden "=" called via dispatching
if Cl1 = Cl2 then [...]
if Cl1 = Cl3 then [...] -- returns false
```

Controlling result (1/2)

- The controlling operand may be the return type
  - This is known as the constructor pattern

```
type Root is tagged null record;
function F (V : Integer) return Root;
```

- If the child adds fields, all such subprograms have to be overridden

```
type Root is tagged null record;
function F (V : Integer) return Root;

type Child is new Root with null record;
--  OK, F is implicitly inherited

type Child1 is new Root with record
   X : Integer;
end record;
--  ERROR no implicitly inherited function F
```

- Primitives returning abstract types have to be abstract

```
type Root is abstract tagged null record;
function F (V : Integer) return Root is abstract;
```

Controlling result (2/2)

- Primitives returning `tagged` types can be used in a static context

```
type Root is tagged null record;
function F return Root;
type Child is new Root with null record;
function F return Child;
V : Root := F;
```

- In a dynamic context, the type has to be known to correctly dispatch

```
V1 : Root'Class := Root'(F);  -- Static call to Root primitive
V2 : Root'Class := V1;
V3 : Root'Class := Child'(F); -- Static call to Child primitive
V4 : Root'Class := F;         -- What is the tag of V4?
...
V1 := F; -- Dispatching call to Root primitive
V2 := F; -- Dispatching call to Root primitive
V3 := F; -- Dispatching call to Child primitive
```

- No dispatching is possible when returning access types

Lab

Polymorphism Lab

- Requirements
  - Create a multi-level types hierarchy of shapes
    - Level 1: Shape → Quadrilateral | Triangle
    - Level 2: Quadrilateral → Square
  - Types should have the following primitive operations
    - Description
    - Number of sides
    - Perimeter
  - Create a main program to print information about multiple shapes
    - Create a nested subprogram that takes a shape and prints all relevant information
- Hints
  - Top-level type should be abstract
    - But can have concrete operations
  - Nested subprogram in **main** should take a shape class parameter

Polymorphism Lab Solution - Shapes (Spec)

```
with Ada.Strings.Unbounded; use Ada.Strings.Unbounded;
package Shapes is
  type Float_T is digits 6;
  type Vertex_T is record
    X : Float_T;
    Y : Float_T;
  end record;
  type Vertices_T is array (Positive range <>) of Vertex_T;

  type Shape_T is abstract tagged record
    Description : Unbounded_String;
  end record;
  function Get_Description (Shape : Shape_T'Class) return String;
  function Number_Of_Sides (Shape : Shape_T) return Natural is abstract;
  function Perimeter (Shape : Shape_T) return Float_T is abstract;

  type Quadrilateral_T is new Shape_T with record
    Sides : Vertices_T (1 .. 4);
  end record;
  function Number_Of_Sides (Shape : Quadrilateral_T) return Natural;
  function Perimeter (Shape : Quadrilateral_T) return Float_T;

  type Square_T is new Quadrilateral_T with null record;
  function Perimeter (Shape : Square_T) return Float_T;

  type Triangle_T is new Shape_T with record
    Sides : Vertices_T (1 .. 3);
  end record;
  function Number_Of_Sides (Shape : Triangle_T) return Natural;
  function Perimeter (Shape : Triangle_T) return Float_T;
end Shapes;
```

Polymorphism Lab Solution - Shapes (Body)

```
with Ada.Numerics.Generic_Elementary_Functions;
package body Shapes is
  package Math is new Ada.Numerics.Generic_Elementary_Functions (Float_T);

  function Distance (Vertex1 : Vertex_T;
                     Vertex2 : Vertex_T)
                     return Float_T is
   (Math.Sqrt ((Vertex1.X - Vertex2.X)**2 + (Vertex1.Y - Vertex2.Y)**2));

  function Perimeter (Vertices : Vertices_T) return Float_T is
    Ret_Val : Float_T := 0.0;
  begin
    for I in Vertices'First .. Vertices'Last - 1 loop
      Ret_Val := Ret_Val + Distance (Vertices (I), Vertices (I + 1));
    end loop;
    Ret_Val := Ret_Val + Distance (Vertices (Vertices'Last), Vertices (Vertices'First));
    return Ret_Val;
  end Perimeter;

  function Get_Description (Shape : Shape_T'Class) return String is (To_String (Shape.Description));

  function Number_Of_Sides (Shape : Quadrilateral_T) return Natural is (4);
  function Perimeter (Shape : Quadrilateral_T) return Float_T is (Perimeter (Shape.Sides));

  function Perimeter (Shape : Square_T) return Float_T is (4.0 * Distance (Shape.Sides (1), Shape.Sides (2)));

  function Number_Of_Sides (Shape : Triangle_T) return Natural is (3);
  function Perimeter (Shape : Triangle_T) return Float_T is (Perimeter (Shape.Sides));
end Shapes;
```

Polymorphism Lab Solution - Main

```
with Ada.Strings.Unbounded; use Ada.Strings.Unbounded;
with Ada.Text_IO;           use Ada.Text_IO;
with Shapes;                use Shapes;
procedure Main is

  Rectangle : constant Shapes.Quadrilateral_T :=
   (Description => To_Unbounded_String ("rectangle"),
    Sides       => ((0.0, 10.0), (0.0, 20.0), (1.0, 20.0), (1.0, 10.0)));
  Triangle : constant Shapes.Triangle_T :=
   (Description => To_Unbounded_String ("triangle"),
    Sides       => ((0.0, 0.0), (0.0, 3.0), (4.0, 0.0)));
  Square : constant Shapes.Square_T :=
   (Description => To_Unbounded_String ("square"),
    Sides       => ((0.0, 1.0), (0.0, 2.0), (1.0, 2.0), (1.0, 1.0)));

  procedure Describe (Shape : Shapes.Shape_T'Class) is
  begin
    Put_Line (Shape.Get_Description);
    if Shape not in Shapes.Shape_T then
      Put_Line ("  Number of sides:" & Integer'Image (Shape.Number_Of_Sides));
      Put_Line ("  Perimeter:" & Shapes.Float_T'Image (Shape.Perimeter));
    end if;
  end Describe;
begin

  Describe (Rectangle);
  Describe (Triangle);
  Describe (Square);
end Main;
```

Summary

Summary

- **'Class** operator
  - Allows subprograms to be used for multiple versions of a type
- Dispatching
  - Abstract types require concrete versions
  - Abstract subprograms allow template definitions
    - Need an implementation for each abstract type referenced
- Run-time call dispatch vs compile-time call dispatching
  - Compiler resolves appropriate call where it can
  - Run-time resolves appropriate call where it can
  - If not resolved, exception

Multiple Inheritance

Introduction

Multiple Inheritance Is Forbidden In Ada

- There are potential conflicts with multiple inheritance
- Some languages allow it: ambiguities have to be resolved when entities are referenced
- Ada forbids it to improve integration

```
type Graphic is tagged record
   X, Y : Float;
end record;
function Get_X (V : Graphic) return Float;

type Shape is tagged record
   X, Y : Float;
end record;
function Get_X (V : Shape) return Float;

type Displayable_Shape is new Shape and Graphic with ...
```

Multiple Inheritance - Safe Case

- If only one type has concrete operations and fields, this is fine

```
type Graphic is abstract tagged null record;
function Get_X (V : Graphic) return Float is abstract;

type Shape is tagged record
   X, Y : Float;
end record;
function Get_X (V : Shape) return Float;

type Displayable_Shape is new Shape and Graphic with ...
```

- This is the definition of an interface (as in Java)

```
type Graphic is interface;
function Get_X (V : Graphic) return Float is abstract;

type Shape is tagged record
   X, Y : Float;
end record;
function Get_X (V : Shape) return Float;

type Displayable_Shape is new Shape and Graphic with ...
```

Interfaces

Interfaces - Rules

- An interface is a tagged type marked interface, containing
  - Abstract primitives
  - Null primitives
  - No fields
- Null subprograms provide default empty bodies to primitives that can be overridden

```
type I is interface;
procedure P1 (V : I) is abstract;
procedure P2 (V : access I) is abstract
function F return I is abstract;
procedure P3 (V : I) is null;
```

- Note: null can be applied to any procedure (not only used for interfaces)

Interface Derivation

- An interface can be derived from another interface, adding primitives

```
type I1 is interface;
procedure P1 (V : I) is abstract;
type I2 is interface and I1;
Procedure P2 (V : I) is abstract;
```

- A tagged type can derive from several interfaces and can derive from one interface several times

```
type I1 is interface;
type I2 is interface and I1;
type I3 is interface;

type R is new I1 and I2 and I3 ...
```

- A tagged type can derive from a single tagged type and several interfaces

```
type I1 is interface;
type I2 is interface and I1;
type R1 is tagged null record;

type R2 is new R1 and I1 and I2 ...
```

Interfaces And Privacy

- If the partial view of the type is tagged, then both the partial and the full view must expose the same interfaces

```
package Types is

   type I1 is interface;
   type R is new I1 with private;

private

   type R is new I1 with record ...
```

Limited Tagged Types And Interfaces

- When a tagged type is limited in the hierarchy, the whole hierarchy has to be limited
- Conversions to interfaces are "just conversions to a view"
  - A view may have more constraints than the actual object
- `limited` interfaces can be implemented by BOTH limited types and non-limited types
- Non-limited interfaces have to be implemented by non-limited types

Lab

Multiple Inheritance Lab

- Requirements
  - Create a tagged type to define shapes
    - Possible components could include location of shape
  - Create an interface to draw lines
    - Possible accessor functions could include line color and width
  - Create a new type inheriting from both of the above for a "printable object"
    - Implement a way to print the object using **Ada.Text_IO**
    - Does not have to be fancy!
  - Create a "printable object" type to draw something (rectangle, triangle, etc)
- Hints
  - This example is taken from Barnes' *Programming in Ada 2012* Section 21.2

Inheritance Lab Solution - Data Types

```
package Base_Types is
   type Coordinate_T is record
      X_Coord : Integer;
      Y_Coord : Integer;
   end record;

   type Line_T is array (1 .. 2) of Coordinate_T;
   -- convert Line_T so lowest X value is first
   function Ordered (Line : Line_T) return Line_T;
   type Lines_T is array (Natural range <>) of Line_T;

   type Color_Range_T is mod 255;
   type Color_T is record
      Red   : Color_Range_T;
      Green : Color_Range_T;
      Blue  : Color_Range_T;
   end record;

private
   function Ordered (Line : Line_T) return Line_T is
     (if Line (1).X_Coord > Line (2).X_Coord then (Line (2), Line (1)) else Line);
end Base_Types;
```

Inheritance Lab Solution - Shapes

```
with Base_Types;
package Geometry is
   type Object_T is abstract tagged private;

private
   type Object_T is abstract tagged record
      Origin : Base_Types.Coordinate_T;
   end record;
   function Origin (Object : Object_T'Class)
                    return Base_Types.Coordinate_T is
      (Object.Origin);
end Geometry;
```

Inheritance Lab Solution - Drawing (Spec)

```
with Base_Types;
package Line_Draw is
   type Object_T is interface;
   procedure Set_Color (Object : in out Object_T;
                        Color  :        Base_Types.Color_T)
                        is abstract;
   function Color (Object : Object_T)
                   return Base_Types.Color_T
                   is abstract;

   Line3  : constant Base_Types.Line_T := ((1, 1), (6, 6));
   Line4  : constant Base_Types.Line_T := ((1, 10), (6, 15))
begin
   Object.Set_Lines ((Line1, Line2, Line3, Line4));
   Object.Print;
end Main;
```

Summary

Summary

- Interfaces must be used for multiple inheritance
  - Usually combined with `tagged` types, but not necessary
  - By using only interfaces, only accessors are allowed
- Typically there are other ways to do the same thing
  - In our example, the conversion routine could be common to simplify things
- But interfaces force the compiler to determine when operations are missing

Advanced Access Types

Introduction

Access Types Design

- Memory addresses objects are called *access types*
- Objects are associated to **pools** of memory
  - With different allocation / deallocation policies

```
type Integer_Pool_Access is access Integer;
P_A : Integer_Pool_Access := new Integer;

type Integer_General_Access is access all Integer;
G : aliased Integer;
G_A1 : Integer_General_Access := G'Access;
G_A2 : Integer_General_Access := new Integer;
```

- This module is mostly about *general access types*

Access Types Can Be Dangerous

- Multiple memory issues
  - Leaks / corruptions
- Introduces potential random failures complicated to analyze
- Increase the complexity of the data structures
- May decrease the performances of the application
  - Dereferences are slightly more expensive than direct access
  - Allocations are a lot more expensive than stacking objects
- Ada avoids using accesses as much as possible
  - Arrays are not pointers
  - Many parameters are implicitly passed by reference
- Only use them when needed

Access Types

Declaration Location

- Can be at library level

```
package P is
  type String_Access is access all String;
end P;
```

- Can be nested in a procedure

```
package body P is
   procedure Proc is
      type String_Access is access all String;
   begin
      ...
   end Proc;
end P;
```

- Nesting adds non-trivial issues
  - Creates a nested pool with a nested accessibility
  - Don't do that unless you know what you are doing! (see later)

Access Types and Primitives

- Subprograms using an access type are primitive of the **access type**
  - **Not** the type of the accessed object

```
type A_T is access all T;
procedure Proc (V : A_T); -- Primitive of A_T, not T
```

- Primitive of the type can be created with the `access` mode
  - **Anonymous** access type

```
procedure Proc (V : access T); -- Primitive of T
```

Anonymous Access Types

- Can be declared in several places
  - Are **general**
- Make sense as parameters of a primitive
- Else, raises a fundamental issue
  - Two different `access T` are **not** compatible

```
procedure Main is
   A : access Integer;
begin
   declare
      type R is record
         A : access Integer;
      end record;

      D : R := (A => new Integer);
   begin
      -- Invalid, and no conversion possible
      A := D.A;
   end;
end Main;
```

Null Values

- A pointer that does not point to any actual data has a `null` value
- Without an initialization, a pointer is `null` by default
- `null` can be used in assignments and comparisons

```
declare
   type Acc is access all Integer;
   V : Acc;
begin
   if V = null then
      --  will go here
   end if
   V := new Integer'(0);
   V := null; -- semantically correct, but memory leak
```

Pool-Specific Access Types

Examples

```
package Pool_Specific is
   type Pointed_To_T is new Integer;
   type Access_T is access Pointed_To_T;
   Object : Access_T := new Pointed_To_T;

   type Other_Access_T is access Pointed_To_T;
   -- Other_Object : Other_Access_T := Other_Access_T ( Object ); -- illegal

   type String_Access_T is access String;
end Pool_Specific;

with Ada.Unchecked_Deallocation;
with Ada.Text_IO;   use Ada.Text_IO;
with Pool_Specific; use Pool_Specific;
procedure Use_Pool_Specific is
   X : Access_T        := new Pointed_To_T'(123);
   Y : String_Access_T := new String (1 .. 10);

   procedure Free is new Ada.Unchecked_Deallocation (Pointed_To_T, Access_T);

begin
   Put_Line (Y.all);
   Y := new String'("String will be long enough to hold this");
   Put_Line (Y.all);
   Put_Line (Pointed_To_T'Image (X.all));
   Free (X);
   Put_Line (Pointed_To_T'Image (X.all)); -- run-time error
end Use_Pool_Specific;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/140_access_types.html#pool-specific-access-types

Pool-Specific Access Type

- An access type is a type

```
type T is [...]
type T_Access is access T;
V : T_Access := new T;
```

- Conversion is **not** possible between pool-specific access types

Allocations

- Objects are created with the **new** reserved word
- The created object must be constrained
  - The constraint is given during the allocation

```
V : String_Access := new String (1 .. 10);
```

- The object can be created by copying an existing object - using a qualifier

```
V : String_Access := new String'("This is a String");
```

Deallocations

- Deallocations are unsafe
  - Multiple deallocations problems
  - Memory corruptions
  - Access to deallocated objects
- As soon as you use them, you lose the safety of your pointers
- But sometimes, you have to do what you have to do ...
  - There's no simple way of doing it
  - Ada provides **Ada.Unchecked_Deallocation**
  - Has to be instantiated (it's a generic)
  - Must work on an object, reset to `null` afterwards

Deallocation Example

```
-- generic used to deallocate memory
with Ada.Unchecked_Deallocation;
procedure P is
   type An_Access is access A_Type;
   -- create instances of deallocation function
   -- (object type, access type)
   procedure Free is new Ada.Unchecked_Deallocation
     (A_Type, An_Access);
   V : An_Access := new A_Type;
begin
   Free (V);
   -- V is now null
end P;
```

General Access Types

General Access Types

- Can point to any pool (including stack)

```
type T is [...]
type T_Access is access all T;
V : T_Access := new T;
```

- Still distinct type
- Conversions are possible

```
type T_Access_2 is access all T;
V2 : T_Access_2 := T_Access_2 (V); -- legal
```

Referencing The Stack

- By default, stack-allocated objects cannot be referenced - and can even be optimized into a register by the compiler
- `aliased` declares an object to be referenceable through an access value

```
V : aliased Integer;
```

- `'Access` attribute gives a reference to the object

```
A : Int_Access := V'Access;
```

  - `'Unchecked_Access` does it **without checks**

Accessibility Checks

Introduction to Accessibility Checks (1/2)

- The depth of an object depends on its nesting within declarative scopes

```
package body P is
   --  Library level, depth 0
   O0 : aliased Integer;
   procedure Proc is
      --  Library level subprogram, depth 1
      type Acc1 is access all Integer;
      procedure Nested is
         -- Nested subprogram, enclosing + 1, here 2
         O2 : aliased Integer;
```

- Access **types** can only access objects that are at **same or lower depth**
- `type Acc1` (depth 1) can access `O0` (depth 0) but not **O2** (depth 2)
- The compiler checks it statically
  - Removing checks is a workaround!
- Note: Subprogram library units are at **depth 1** and not 0

Introduction to Accessibility Checks (2/2)

- Issues with nesting

```
package body P is
   type T0 is access all Integer;
   A0 : T0;
   V0 : aliased Integer;

   procedure Proc is
      type T1 is access all Integer;
      A1 : T1;
      V1 : aliased Integer;
   begin
      A0 := V0'Access;
      -- A0 := V1'Access; -- illegal
      A0 := V1'Unchecked_Access;
      A1 := V0'Access;
      A1 := V1'Access;
      A1 := T1 (A0);
      A1 := new Integer;
      -- A0 := T0 (A1); -- illegal
  end Proc;
end P;
```

- Simple workaround is to avoid nested access types

Dynamic Accessibility Checks

- Following the same rules
  - Performed dynamically by the runtime
- Lots of possible cases
  - New compiler versions may detect more cases
  - Using access always requires proper debugging and reviewing

```
procedure Main is
   type Acc is access all Integer;
   O : Acc;

   procedure Set_Value (V : access Integer) is
   begin
      O := Acc (V);
   end Set_Value;
begin
   declare
      O2 : aliased Integer := 2;
   begin
      Set_Value (O2'Access);
   end;
end Main;
```

Getting Around Accessibility Checks

- Sometimes it is OK to use unsafe accesses to data
- `'Unchecked_Access` allows access to a variable of an incompatible accessibility level
- Beware of potential problems!

```
type Acc is access all Integer;
G : Acc;
procedure P is
   V : aliased Integer;
begin
   G := V'Unchecked_Access;
   ...
   Do_Something ( G.all ); -- This is "reasonable"
end P;
```

Using Pointers For Recursive Structures

- It is not possible to declare recursive structure
- But there can be an access to the enclosing type

```
type Cell; -- partial declaration
type Cell_Access is access all Cell;
type Cell is record -- full declaration
   Next       : Cell_Access;
   Some_Value : Integer;
end record;
```

Memory Corruption

Common Memory Problems (1/3)

- Uninitialized pointers

```
declare
   type An_Access is access all Integer;
   V : An_Access;
begin
   V.all := 5; -- constraint error
```

- Double deallocation

```
declare
   type An_Access is access all Integer;
   procedure Free is new
      Ada.Unchecked_Deallocation (Integer, An_Access);
   V1 : An_Access := new Integer;
   V2 : An_Access := V1;
begin
   Free (V1);
   ...
   Free (V2);
```

  - May raise `Storage_Error` if memory is still protected (unallocated)
  - May deallocate a different object if memory has been reallocated
    - Putting that object in an inconsistent state

Common Memory Problems (2/3)

- Accessing deallocated memory

```
declare
   type An_Access is access all Integer;
   procedure Free is new
      Ada.Unchecked_Deallocation (Integer, An_Access);
   V1 : An_Access := new Integer;
   V2 : An_Access := V1;
begin
   Free (V1);
   ...
   V2.all := 5;
```

  - May raise `Storage_Error` if memory is still protected (unallocated)
  - May modify a different object if memory has been reallocated (putting that object in an inconsistent state)

Common Memory Problems (3/3)

- Memory leaks

```
declare
   type An_Access is access all Integer;
   procedure Free is new
      Ada.Unchecked_Deallocation (Integer, An_Access);
   V : An_Access := new Integer;
begin
   V := null;
```

  - Silent problem
    - Might raise `Storage_Error` if too many leaks
    - Might slow down the program if too many page faults

How To Fix Memory Problems?

- There is no language-defined solution
- Use the debugger!
- Use additional tools
  - `gnatmem` monitor memory leaks
  - `valgrind` monitor all the dynamic memory
  - **GNAT.Debug_Pools** gives a pool for an access type, raising explicit exception in case of invalid access
  - Others...

Memory Management

Simple Linked List

- A linked list object typically consists of:
  - Content
  - "Indication" of next item in list
    - Fancier linked lists may reference previous item in list
- "Indication" is just a pointer to another linked list object
  - Therefore, self-referencing
- Ada does not allow a record to self-reference

Incomplete Types

- In Ada, an *incomplete type* is just the word `type` followed by the type name
  - Optionally, the name may be followed by `(<>)` to indicate the full type may be unconstrained
- Ada allows access types to point to an incomplete type
  - Just about the only thing you *can* do with an incomplete type!

```
type Some_Record_T;
type Some_Record_Access_T is access all Some_Record_T;

type Unconstrained_Record_T (<>);
type Unconstrained_Record_Access_T is access all Unconstrained_Record_T;

type Some_Record_T is record
   Field : String (1 .. 10);
end record;

type Unconstrained_Record_T (Size : Index_T) is record
   Field : String (1 .. Size);
end record;
```

Linked List in Ada

- Now that we have a pointer to the record type (by name), we can use it in the full definition of the record type

```
type Some_Record_T is record
   Field : String (1 .. 10);
   Next  : Some_Record_Access_T;
end record;

type Unconstrained_Record_T (Size : Index_T) is record
   Field    : String (1 .. Size);
   Next     : Unconstrained_Record_Access_T;
   Previous : Unconstrained_Record_Access_T;
end record;
```

Simplistic Linked List

```
with Ada.Text_IO; use Ada.Text_IO;
with Ada.Unchecked_Deallocation;
procedure Simple is
   type Some_Record_T;
   type Some_Record_Access_T is access all Some_Record_T;
   type Some_Record_T is record
      Field : String (1 .. 10);
      Next  : Some_Record_Access_T;
   end record;

   Head : Some_Record_Access_T := null;
   Item : Some_Record_Access_T := null;

   Line : String (1 .. 10);
   Last : Natural;

 procedure Free is new Ada.Unchecked_Deallocation
   (Some_Record_T, Some_Record_Access_T);

begin

   loop
      Put ("Enter String: ");
      Get_Line (Line, Last);
      exit when Last = 0;
      Line (Last + 1 .. Line'last) := (others => ' ');
      Item                         := new Some_Record_T;
      Item.all                     := (Line, Head);
      Head                         := Item;
   end loop;

   Put_Line ("List");
   while Head /= null loop
      Put_Line ("  " & Head.Field);
      Head := Head.Next;
   end loop;

   Put_Line ("Delete");
   Free (Item);
   GNAT.Debug_Pools.Print_Info_Stdout (Storage_Pool);

end Simple;
```

Memory Debugging

GNAT.Debug_Pools

- Ada allows the coder to specify *where* the allocated memory comes from
  - Called *Storage Pool*
  - Basically, connecting `new` and `Unchecked_Deallocation` with some other code
  - More details in the next section

```
type Linked_List_Ptr_T is access all Linked_List_T;
for Linked_List_Ptr_T'storage_pool use Memory_Mgmt.Storage_Pool;
```

- GNAT uses this mechanism in the run-time package `GNAT.Debug_Pools` to track allocation/deallocation

```
with GNAT.Debug_Pools;
package Memory_Mgmt is
  Storage_Pool : GNAT.Debug_Pools.Debug_Pool;
end Memory_Mgmt;
```

GNAT.Debug_Pools Spec (Partial)

```
package GNAT.Debug_Pools is

   type Debug_Pool is new System.Checked_Pools.Checked_Pool with private;

   generic
      with procedure Put_Line (S : String) is <>;
      with procedure Put      (S : String) is <>;
   procedure Print_Info
     (Pool          : Debug_Pool;
      Cumulate      : Boolean := False;
      Display_Slots : Boolean := False;
      Display_Leaks : Boolean := False);

   procedure Print_Info_Stdout
     (Pool          : Debug_Pool;
      Cumulate      : Boolean := False;
      Display_Slots : Boolean := False;
      Display_Leaks : Boolean := False);
   --  Standard instantiation of Print_Info to print on standard_output.

   procedure Dump_Gnatmem (Pool : Debug_Pool; File_Name : String);
   --  Create an external file on the disk, which can be processed by gnatmem
   --  to display the location of memory leaks.

   procedure Print_Pool (A : System.Address);
   --  Given an address in memory, it will print on standard output the known
   --  information about this address

   function High_Water_Mark
     (Pool : Debug_Pool) return Byte_Count;
   --  Return the highest size of the memory allocated by the pool.

   function Current_Water_Mark
     (Pool : Debug_Pool) return Byte_Count;
   --  Return the size of the memory currently allocated by the pool.

private
   -- ...
end GNAT.Debug_Pools;
```

Displaying Debug Information

- Simple modifications to our linked list example
  - Create and use storage pool

```
with GNAT.Debug_Pools; -- Added
procedure Simple is
   Storage_Pool : GNAT.Debug_Pools.Debug_Pool; -- Added
   type Some_Record_T;
   type Some_Record_Access_T is access all Some_Record_T;
   for Some_Record_Access_T'storage_pool
       use Storage_Pool; -- Added
```

  - Dump info after each `new`

```
Item                              := new Some_Record_T;
GNAT.Debug_Pools.Print_Info_Stdout (Storage_Pool); -- Added
Item.all := (Line, Head);
```

  - Dump info after `free`

```
Free (Item);
GNAT.Debug_Pools.Print_Info_Stdout (Storage_Pool); -- Added
```

Execution Results

```
Enter String: X
Total allocated bytes :  24
Total logically deallocated bytes :  0
Total physically deallocated bytes :  0
Current Water Mark:  24
High Water Mark:  24

Enter String: Y
Total allocated bytes :  48
Total logically deallocated bytes :  0
Total physically deallocated bytes :  0
Current Water Mark:  48
High Water Mark:  48

Enter String:
List
  Y
  X
Delete
Total allocated bytes :  48
Total logically deallocated bytes :  24
Total physically deallocated bytes :  0
Current Water Mark:  24
High Water Mark:  48
```

Memory Control

System.Storage_Pools

- Mechanism to allow coder control over allocation/deallocation process
  - Uses `Ada.Finalization.Limited_Controlled` to implement customized memory allocation and deallocation.
  - Must be specified for each access type being controlled

```
type Boring_Access_T is access Some_T;
-- Storage Pools mechanism not used here
type Important_Access_T is access Some_T;
for Important_Access_T'storage_pool use My_Storage_Pool;
-- Storage Pools mechanism used for Important_Access_T
```

System.Storage_Pools Spec (Partial)

```
with Ada.Finalization;
with System.Storage_Elements;
package System.Storage_Pools with Pure is
  type Root_Storage_Pool is abstract
    new Ada.Finalization.Limited_Controlled with private;
  pragma Preelaborable_Initialization (Root_Storage_Pool);

  procedure Allocate
    (Pool                     : in out Root_Storage_Pool;
     Storage_Address          : out System.Address;
     Size_In_Storage_Elements : System.Storage_Elements.Storage_Count;
     Alignment                : System.Storage_Elements.Storage_Count)
  is abstract;

  procedure Deallocate
    (Pool                     : in out Root_Storage_Pool;
     Storage_Address          : System.Address;
     Size_In_Storage_Elements : System.Storage_Elements.Storage_Count;
     Alignment                : System.Storage_Elements.Storage_Count)
  is abstract;

  function Storage_Size
    (Pool : Root_Storage_Pool)
     return System.Storage_Elements.Storage_Count
  is abstract;

private
  -- ...
end System.Storage_Pools;
```

System.Storage_Pools Explanations

- Note `Root_Storage_Pool`, `Allocate`, `Deallocate`, and `Storage_Size` are **`abstract`**
  - You must create your own type derived from `Root_Storage_Pool`
  - You must create versions of `Allocate`, `Deallocate`, and `Storage_Size` to allocate/deallocate memory
- Parameters
  - `Pool`
    - Memory pool being manipulated
  - `Storage_Address`
    - For `Allocate` - location in memory where access type will point to
    - For `Deallocate` - location in memory where memory should be released
  - `Size_In_Storage_Elements`
    - Number of bytes needed to contain contents
  - `Alignment`
    - Byte alignment for memory location

System.Storage_Pools Example (Partial)

```
subtype Index_T is Storage_Count range 1 .. 1_000;
Memory_Block : aliased array (Index_T) of Interfaces.Unsigned_8;
Memory_Used  : array (Index_T) of Boolean := (others => False);

procedure Set_In_Use (Start  : Index_T;
                      Length : Storage_Count;
                      Used   : Boolean);

function Find_Free_Block (Length : Storage_Count) return Index_T;

procedure Allocate
  (Pool                     : in out Storage_Pool_T;
   Storage_Address          :    out System.Address;
   Size_In_Storage_Elements :        Storage_Count;
   Alignment                :        Storage_Count) is
   Index : Storage_Count := Find_Free_Block (Size_In_Storage_Elements);
begin
   Storage_Address := Memory_Block (Index)'address;
   Set_In_Use (Index, Size_In_Storage_Elements, True);
end Allocate;

procedure Deallocate
  (Pool                     : in out Storage_Pool_T;
   Storage_Address          :        System.Address;
   Size_In_Storage_Elements :        Storage_Count;
   Alignment                :        Storage_Count) is
begin
   for I in Memory_Block'range loop
      if Memory_Block (I)'address = Storage_Address then
         Set_In_Use (I, Size_In_Storage_Elements, False);
      end if;
   end loop;
end Deallocate;
```

Lab

Advanced Access Types Lab

- Build an application that adds / removes items from a linked list
  - At any time, user should be able to
    - Add a new item into the "appropriate" location in the list
    - Remove an item without changing the position of any other item in the list
    - Print the list
- This is a multi-step lab! First priority should be understanding linked lists, then, if you have time, storage pools
- Required goals
  1. Implement **Add** functionality
     - For this step, "appropriate" means either end of the list (but consistent - always front or always back)
  2. Implement **Print** functionality
  3. Implement **Delete** functionality

Extra Credit

- Complete as many of these as you have time for
  1. Use `GNAT.Debug_Pools` to print out the status of your memory allocation/deallocation after every `new` and `deallocate`
  2. Modify **Add** so that "appropriate" means in a sorted order
  3. Implement storage pools where you write your own memory allocation/deallocation routines
     - Should still be able to print memory status

Lab Solution - Database

```
with Ada.Strings.Unbounded;
package Database is
   type Database_T is private;
   function "=" (L, R : Database_T) return Boolean;
   function To_Database (Value : String) return Database_T;
   function From_Database (Value : Database_T) return String;
   function "<" (L, R : Database_T) return Boolean;
private
   type Database_T is record
      Value  : String (1 .. 100);
      Length : Natural;
   end record;
end Database;

package body Database is
   use Ada.Strings.Unbounded;
   function "=" (L, R : Database_T) return Boolean is
   begin
      return L.Value (1 .. L.Length) = R.Value (1 .. R.Length);
   end "=";
   function To_Database (Value : String) return Database_T is
      Retval : Database_T;
   begin
      Retval.Length                      := Value'length;
      Retval.Value (1 .. Retval.Length) := Value;
      return Retval;
   end To_Database;
   function From_Database (Value : Database_T) return String is
   begin
      return Value.Value (1 .. Value.Length);
   end From_Database;

   function "<" (L, R : Database_T) return Boolean is
   begin
      return L.Value (1 .. L.Length) < R.Value (1 .. R.Length);
   end "<";
end Database;
```

Lab Solution - Database_List (Spec)

```
with Database; use Database;
-- Uncomment next line when using debug/storage pools
-- with Memory_Mgmt;
package Database_List is
   type List_T is limited private;
   procedure First (List : in out List_T);
   procedure Next (List : in out List_T);
   function End_Of_List (List : List_T) return Boolean;
   function Current (List : List_T) return Database_T;
   procedure Insert (List    : in out List_T;
                     Element :        Database_T);
   procedure Delete (List    : in out List_T;
                     Element :        Database_T);
   function Is_Empty (List : List_T) return Boolean;
private
   type Linked_List_T;
   type Linked_List_Ptr_T is access all Linked_List_T;
   -- Uncomment next line when using debug/storage pools
   -- for Linked_List_Ptr_T'storage_pool use Memory_Mgmt.Storage_Pool;
   type Linked_List_T is record
      Next    : Linked_List_Ptr_T;
      Content : Database_T;
   end record;
   type List_T is record
      Head    : Linked_List_Ptr_T;
      Current : Linked_List_Ptr_T;
   end record;
end Database_List;
```

Lab Solution - Database_List (Helper Objects)

```
with Interfaces;
with Unchecked_Deallocation;
package body Database_List is
   use type Database.Database_T;

   function Is_Empty (List : List_T) return Boolean is
   begin
      return List.Head = null;
   end Is_Empty;

   procedure First (List : in out List_T) is
   begin
      List.Current := List.Head;
   end First;

   procedure Next (List : in out List_T) is
   begin
      if not Is_Empty (List) then
         if List.Current /= null then
            List.Current := List.Current.Next;
         end if;
      end if;
   end Next;

   function End_Of_List (List : List_T) return Boolean is
   begin
      return List.Current = null;
   end End_Of_List;

   function Current (List : List_T) return Database_T is
   begin
      return List.Current.Content;
   end Current;
```

Lab Solution - Database_List (Insert/Delete)

```
   procedure Insert (List    : in out List_T;
                     Element :        Database_T) is
      New_Element : Linked_List_Ptr_T :=
        new Linked_List_T'(Next => null, Content => Element);
   begin
      if Is_Empty (List) then
         List.Current := New_Element;
         List.Head    := New_Element;
      elsif Element < List.Head.Content then
         New_Element.Next := List.Head;
         List.Current     := New_Element;
         List.Head        := New_Element;
      else
         declare
            Current : Linked_List_Ptr_T := List.Head;
         begin
            while Current.Next /= null and then Current.Next.Content < Element
            loop
               Current := Current.Next;
            end loop;
            New_Element.Next := Current.Next;
            Current.Next     := New_Element;
         end;
      end if;
      -- Uncomment next line when using debug/storage pools
      -- Memory_Mgmt.Print_Info;
   end Insert;

   procedure Free is new Unchecked_Deallocation
     (Linked_List_T, Linked_List_Ptr_T);
   procedure Delete
     (List    : in out List_T;
      Element :        Database_T) is
      To_Delete : Linked_List_Ptr_T := null;
   begin
      if not Is_Empty (List) then
         if List.Head.Content = Element then
            To_Delete    := List.Head;
            List.Head    := List.Head.Next;
            List.Current := List.Head;
         else
            declare
               Previous : Linked_List_Ptr_T := List.Head;
               Current  : Linked_List_Ptr_T := List.Head.Next;
            begin
               while Current /= null loop
                  if Current.Content = Element then
                     To_Delete     := Current;
                     Previous.Next := Current.Next;
                  end if;
                  Current := Current.Next;
               end loop;
            end;
            List.Current := List.Head;
         end if;
         if To_Delete /= null then
            Free (To_Delete);
         end if;
      end if;
      -- Uncomment next line when using debug/storage pools
      -- Memory_Mgmt.Print_Info;
   end Delete;
end Database_List;
```

Lab Solution - Main

```
with Simple_Io; use Simple_Io;
with Database;
with Database_List;
procedure Main is
   List    : Database_List.List_T;
   Element : Database.Database_T;

   procedure Add is
      Value : constant String := Get_String ("Add");
   begin
      if Value'length > 0 then
         Element := Database.To_Database (Value);
         Database_List.Insert (List, Element);
      end if;
   end Add;

   procedure Delete is
      Value : constant String := Get_String ("Delete");
   begin
      if Value'length > 0 then
         Element := Database.To_Database (Value);
         Database_List.Delete (List, Element);
      end if;
   end Delete;

   procedure Print is
   begin
      Database_List.First (List);
      Simple_Io.Print_String ("List");
      while not Database_List.End_Of_List (List) loop
         Element := Database_List.Current (List);

        ("High Water Mark: " & Storage_Count'image (High_Water_Mark));
   end Print_Info;

end Memory_Mgmt;
```

Summary

Summary

- Access types when used with "dynamic" memory allocation can cause problems
  - Whether actually dynamic or using managed storage pools, memory leaks/lack can occur
  - Storage pools can help diagnose memory issues, but it's still a usage issue
- `GNAT.Debug_Pools` is useful for debugging memory issues
  - Mostly in low-level testing
  - Could integrate it with an error logging mechanism
- `System.Storage_Pools` can be used to control memory usage
  - Adds overhead

Limited Types

Introduction

Views

- Specify how values and objects may be manipulated
- Are implicit in much of the language semantics
  - Constants are just variables without any assignment view
  - Task types, protected types implicitly disallow assignment
  - Mode **in** formal parameters disallow assignment

```
Variable : Integer := 0;
...
-- P's view of X prevents modification
procedure P( X :  in  Integer ) is
begin
    ...
end P;
...
P( Variable );
```

Limited Type Views' Semantics

- Prevents copying via predefined assignment
  - Disallows assignment between objects
  - Must make your own **copy** procedure if needed

```
type File is limited ...
...
F1, F2 : File;
...
F1 := F2; -- compile error
```

- Prevents incorrect comparison semantics
  - Disallows predefined equality operator
  - Make your own equality function = if needed

Inappropriate Copying Example

```
type File is ...
F1, F2 : File;
...
Open (F1);
Write ( F1, "Hello" );
-- What is this assignment really trying to do?
F2 := F1;
```

Intended Effects of Copying

```
type File is ...
F1, F2 : File;
...
Open (F1);
Write ( F1, "Hello" );
Copy (Source => F1, Target => F2);
```

Declarations

Examples

```
with Interfaces;
package Multiprocessor_Mutex is
   subtype Id_T is String (1 .. 4);
   -- prevent copying of a lock
   type Limited_T is limited record
      Flag : Interfaces.Unsigned_8;
   end record;
   type Also_Limited_T is record
      Lock : Limited_T;
      Id   : Id_T;
   end record;
   procedure Lock (This : in out Also_Limited_T) is null;
   procedure Unlock (This : in out Also_Limited_T) is null;
end Multiprocessor_Mutex;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/120_limited_types.html#declarations

Limited Type Declarations

- Syntax
  - Additional keyword limited added to record type declaration

```
type defining_identifier is limited record
    component_list
end record;
```

- Are always record types unless also private
  - More in a moment...

Approximate Analog In C++

```
class Stack {
public:
   Stack();
   void Push (int X);
   void Pop (int& X);
   ...
private:
   ...
   // assignment operator hidden
   Stack& operator= (const Stack& other);
}; // Stack
```

Spin Lock Example

```
with Interfaces;
package Multiprocessor_Mutex is
   -- prevent copying of a lock
   type Spin_Lock is limited record
     Flag : Interfaces.Unsigned_8;
   end record;
   procedure Lock   (This : in out Spin_Lock);
   procedure Unlock  (This : in out Spin_Lock);
   pragma Inline (Lock, Unlock);
end Multiprocessor_Mutex;
```

Parameter Passing Mechanism

- Always "by-reference" if explicitly limited
  - Necessary for various reasons (`task` and `protected` types, etc)
  - Advantageous when required for proper behavior
- By definition, these subprograms would be called concurrently
  - Cannot operate on copies of parameters!

```
procedure Lock   (This : in out Spin_Lock);
procedure Unlock (This : in out Spin_Lock);
```

Composites with Limited Types

- Composite containing a limited type becomes limited as well
  - Example: Array of limited elements
    - Array becomes a limited type
  - Prevents assignment and equality loop-holes

```
declare
   -- if we can't copy component S, we can't copy User_Type
   type User_Type is record -- limited because S is limited
      S : File;
      ...
   end record;
   A, B : User_Type;
begin
   A := B;  -- not legal since limited
   ...
end;
```

Quiz

```
type T is limited record
   I : Integer;
end record;

L1, L2 : T;
B : Boolean;
```

Which statement(s) is(are) legal?

A. `L1.I := 1`
B. `L1 := L2`
C. `B := (L1 = L2)`
D. `B := (L1.I = L2.I)`

Quiz

```
type T is limited record
   I : Integer;
end record;

L1, L2 : T;
B : Boolean;
```

Which statement(s) is(are) legal?

A. *L1.I := 1*
B. L1 := L2
C. B := (L1 = L2)
D. *B := (L1.I = L2.I)*

Quiz

```
type T is limited record
   I : Integer;
end record;
```

Which of the following declaration(s) is(are) legal?

A. `function "+" (A : T) return T is (A)`
B. `function "-" (A : T) return T is (I => -A.I)`
C. `function "=" (A, B : T) return Boolean is (True)`
D. `function "=" (A, B : T) return Boolean is (A.I = T'(I => B.I).I)`

Quiz

```
type T is limited record
   I : Integer;
end record;
```

Which of the following declaration(s) is(are) legal?

A. `function "+" (A : T) return T is (A)`
B. *`function "-" (A : T) return T is (I => -A.I)`*
C. *`function "=" (A, B : T) return Boolean is (True)`*
D. *`function "=" (A, B : T) return Boolean is (A.I = T'(I => B.I).I)`*

Quiz

```
package P is
   type T is limited null record;
   type R is record
      F1 : Integer;
      F2 : T;
   end record;
end P;

with P;
procedure Main is
   T1, T2 : P.T;
   R1, R2 : P.R;
begin
```

Which assignment is legal?

A. `T1    := T2;`
B. `R1    := R2;`
C. `R1.F1 := R2.F1;`
D. `R2.F2 := R2.F2;`

Quiz

```
package P is
   type T is limited null record;
   type R is record
      F1 : Integer;
      F2 : T;
   end record;
end P;

with P;
procedure Main is
   T1, T2 : P.T;
   R1, R2 : P.R;
begin
```

Which assignment is legal?

A. `T1    := T2;`
B. `R1    := R2;`
C. ***`R1.F1 := R2.F1;`***
D. `R2.F2 := R2.F2;`

Explanations

A. `T1` and `T2` are **`limited`** types
B. `R1` and `R2` contain **`limited`** types so they are also **`limited`**
C. Theses components are not **`limited`** types
D. These components are of a **`limited`** type

Creating Values

Examples

```
with Interfaces;
package Multiprocessor_Mutex is
   subtype Id_T is String (1 .. 4);
   -- prevent copying of a lock
   type Limited_T is limited record
      Flag : Interfaces.Unsigned_8;
   end record;
   type Also_Limited_T is record
      Lock : Limited_T;
      Id   : Id_T;
   end record;
   procedure Lock (This : in out Also_Limited_T);
   procedure Unlock (This : in out Also_Limited_T);
   function Create (Flag : Interfaces.Unsigned_8;
                    Id   : Id_T)
                    return Also_Limited_T;
end Multiprocessor_Mutex;

package body Multiprocessor_Mutex is
   procedure Lock (This : in out Also_Limited_T) is null;
   procedure Unlock (This : in out Also_Limited_T) is null;
   Global_Lock : Also_Limited_T := (Lock => (Flag => 0), Id => "GLOB");
   function Create (Flag : Interfaces.Unsigned_8;
                    Id   : Id_T)
                    return Also_Limited_T is
      Local_Lock : Also_Limited_T := (Lock => (Flag => 1), Id => "LOCA");
   begin
      Global_Lock.Lock.Flag := Flag;
      Local_Lock.Id         := Id;
      -- Compile error
      -- return Local_Lock;
      -- Compile error
      -- return Global_Lock;
      return (Lock => (Flag => Flag), Id => Id);
   end Create;
end Multiprocessor_Mutex;

with Ada.Text_IO;          use Ada.Text_IO;
with Multiprocessor_Mutex; use Multiprocessor_Mutex;
procedure Perform_Lock is
   Lock1 : Also_Limited_T := (Lock => (Flag => 2), Id => "LOCK");
   Lock2 : Also_Limited_T;
begin
   -- Lock2 := Create ( 3, "CREA" ); -- illegal
   Put_Line (Lock1.Id & Lock1.Lock.Flag'Image);
end Perform_Lock;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/120_limited_types.html#creating-values

Creating Values

- Initialization is not assignment (but looks like it)!
- Via **limited constructor functions**
  - Functions returning values of limited types
- Via an **aggregate**
  - *limited aggregate* when used for a `limited` type

```
type Spin_Lock is limited record
   Flag : Interfaces.Unsigned_8;
end record;
...
Mutex : Spin_Lock := (Flag => 0); -- limited aggregate
```

Limited Constructor Functions

- Allowed wherever limited aggregates are allowed
- More capable (can perform arbitrary computations)
- Necessary when limited type is also private
  - Users won't have visibility required to express aggregate contents

```
function F return Spin_Lock
is
begin
   ...
   return (Flag => 0);
end F;
```

Writing Limited Constructor Functions

- Remember - copying is not allowed

```
function F return Spin_Lock is
  Local_X : Spin_Lock;
begin
  ...
  return Local_X; -- this is a copy - not legal
   -- (also illegal because of pass-by-reference)
end F;

Global_X : Spin_Lock;
function F return Spin_Lock is
begin
  ...
  -- This is not legal staring with Ada2005
  return Global_X; -- this is a copy
end F;
```

"Built In-Place"

- Limited aggregates and functions, specifically
- No copying done by implementation
  - Values are constructed in situ

```
Mutex : Spin_Lock := (Flag => 0);

function F return Spin_Lock is
begin
   return (Flag => 0);
end F;
```

Quiz

```
type T is limited record
   I : Integer;
end record;
```

Which piece(s) of code is(are) a legal constructor for T?

A.
```
function F return T is
begin
  return T (I => 0);
end F;
```

B.
```
function F return T is
  Val :  Integer := 0;
begin
  return (I => Val);
end F;
```

C.
```
function F return T is
  Ret : T := (I => 0);
begin
  return Ret;
end F;
```

D.
```
function F return T is
begin
  return (0);
end F;
```

Quiz

```
type T is limited record
   I : Integer;
end record;
```

Which piece(s) of code is(are) a legal constructor for T?

A.
```
function F return T is
begin
  return T (I => 0);
end F;
```

B.
```
function F return T is
   Val :  Integer := 0;
begin
  return (I => Val);
end F;
```

C.
```
function F return T is
   Ret : T := (I => 0);
begin
  return Ret;
end F;
```

D.
```
function F return T is
begin
  return (0);
end F;
```

Quiz

```
package P is
   type T is limited record
      F1 : Integer;
      F2 : Character;
   end record;
   Zero : T := (0, ' ');
   One : constant T := (1, 'a');
   Two : T;
   function F return T;
end P;
```

Which is a correct completion of F?

A. `return (3, 'c');`

B.
```
Two := (2, 'b');
return Two;
```

C. `return One;`

D. `return Zero;`

Quiz

```
package P is
   type T is limited record
      F1 : Integer;
      F2 : Character;
   end record;
   Zero : T := (0, ' ');
   One : constant T := (1, 'a');
   Two : T;
   function F return T;
end P;
```

Which is a correct completion of F?

A. `return (3, 'c');`

B.
```
Two := (2, 'b');
return Two;
```

C. `return One;`

D. `return Zero;`

A contains an "in-place" return. The rest all rely on other objects, which would require an (illegal) copy.

Extended Return Statements

Examples

```
with Interfaces; use Interfaces;
package Multiprocessor_Mutex is
   subtype Id_T is String (1 .. 4);
   -- prevent copying of a lock
   type Limited_T is limited record
      Flag : Interfaces.Unsigned_8;
   end record;
   type Also_Limited_T is record
      Lock : Limited_T;
      Id   : Id_T;
   end record;
   procedure Lock (This : in out Also_Limited_T);
   procedure Unlock (This : in out Also_Limited_T);
   function Create (Id : Id_T) return Also_Limited_T;
end Multiprocessor_Mutex;

package body Multiprocessor_Mutex is
   procedure Lock (This : in out Also_Limited_T) is null;
   procedure Unlock (This : in out Also_Limited_T) is null;

   Global_Lock_Counter : Interfaces.Unsigned_8 := 0;
   function Create (Id : Id_T) return Also_Limited_T is
   begin
      return Ret_Val : Also_Limited_T do
         if Global_Lock_Counter = Interfaces.Unsigned_8'Last then
            return;
         end if;
         Global_Lock_Counter := Global_Lock_Counter + 1;
         Ret_Val.Id          := Id;
         Ret_Val.Lock.Flag   := Global_Lock_Counter;
      end return;
   end Create;
end Multiprocessor_Mutex;

with Ada.Text_IO;          use Ada.Text_IO;
with Multiprocessor_Mutex; use Multiprocessor_Mutex;
procedure Perform_Lock is
   Lock1 : constant Also_Limited_T := Create ("One ");
   Lock2 : constant Also_Limited_T := Create ("Two ");
begin
   Put_Line (Lock1.Id & Lock1.Lock.Flag'Image);
   Put_Line (Lock2.Id & Lock2.Lock.Flag'Image);
end Perform_Lock;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/120_limited_types.html#extended-return-statements

Function Extended Return Statements

Ada 2005

- *Extended return*
- Result is expressed as an object
- More expressive than aggregates
- Handling of unconstrained types
- Syntax (simplified):

```
return identifier : subtype [:= expression];

return identifier : subtype
[do
   sequence_of_statements ...
 end return];
```

Extended Return Statements Example

```
--  Implicitly limited array
type Spin_Lock_Array (Positive range <>) of Spin_Lock;

function F return Spin_Lock_Array is
begin
  return Result : Spin_Lock_Array (1 .. 10) do
     ...
  end return;
end F;
```

Expression / Statements Are Optional

Ada 2005

- Without sequence (returns default if any)

```
function F return Spin_Lock is
begin
   return Result : Spin_Lock;
end F;
```

- With sequence

```
function F return Spin_Lock is
   X : Interfaces.Unsigned_8;
begin
   --  compute X ...
   return Result : Spin_Lock := (Flag => X);
end F;
```

Statements Restrictions

Ada 2005

- **No** nested extended return
- **Simple** return statement **allowed**
  - **Without** expression
  - Returns the value of the **declared object** immediately

```
function F return Spin_Lock is
begin
  return Result : Spin_Lock do
    if Set_Flag then
      Result.Flag := 1;
      return;  --  returns 'Result'
    end if;
    Result.Flag := 0;
  end return; --  Implicit return
end F;
```

Quiz

```
type T is limited record
   I : Integer;
end record;

function F return T is
begin
   -- F body...
end F;

O : T := F;
```

Which declaration(s) of `F` is(are) valid?

A. `return Return : T := (I => 1)`

B. `return Result :  T`

C. `return Value := (others => 1)`

D.
```
return R : T do
   R.I := 1;
end return;
```

Quiz

```
type T is limited record
   I : Integer;
end record;

function F return T is
begin
   -- F body...
end F;

O : T := F;
```

Which declaration(s) of `F` is(are) valid?

A. `return Return : T := (I => 1)`

B. `return Result :  T`

C. `return Value := (others => 1)`

D.
```
return R : T do
   R.I := 1;
end return;
```

A. Using **return** reserved keyword
B. OK, default value
C. Extended return must specify type
D. OK

Combining Limited and Private Views

Examples

```
with Interfaces; use Interfaces;
package Multiprocessor_Mutex is
   type Limited_T is limited private;
   procedure Lock (This : in out Limited_T);
   procedure Unlock (This : in out Limited_T);
   function Create return Limited_T;
private
   type Limited_T is limited -- no internal copying allowed
   record
      Flag : Interfaces.Unsigned_8; -- users cannot see this
   end record;
end Multiprocessor_Mutex;

package body Multiprocessor_Mutex is
   procedure Lock (This : in out Limited_T) is null;
   procedure Unlock (This : in out Limited_T) is null;

   Global_Lock_Counter : Interfaces.Unsigned_8 := 0;
   function Create return Limited_T is
   begin
      return Ret_Val : Limited_T do
         Global_Lock_Counter := Global_Lock_Counter + 1;
         Ret_Val.Flag        := Global_Lock_Counter;
      end return;
   end Create;
end Multiprocessor_Mutex;

with Multiprocessor_Mutex; use Multiprocessor_Mutex;
package Use_Limited_Type is
   type Legal is limited private;
   type Also_Legal is limited private;
   -- type Not_Legal is private;
   -- type Also_Not_Legal is private;
private
   type Legal is record
      S : Limited_T;
   end record;
   type Also_Legal is limited record
      S : Limited_T;
   end record;
   -- type Not_Legal is limited record
   --    S : Limited_T;
   -- end record;
   -- type Also_Not_Legal is record
   --    S : Limited_T;
   -- end record;
end Use_Limited_Type;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/120_limited_types.html#combining-limited-and-private-views

Limited Private Types

- A combination of `limited` and `private` views
  - No client compile-time visibility to representation
  - No client assignment or predefined equality
- The typical design idiom for `limited` types
- Syntax
  - Additional reserved word `limited` added to `private` type declaration

```
type defining_identifier is limited private;
```

Limited Private Type Rationale (1)

```
package Multiprocessor_Mutex is
   -- copying is prevented
   type Spin_Lock is limited record
      -- but users can see this!
      Flag : Interfaces.Unsigned_8;
   end record;
   procedure Lock (This : in out Spin_Lock);
   procedure Unlock (This : in out Spin_Lock);
   pragma Inline (Lock, Unlock);
end Multiprocessor_Mutex;
```

Limited Private Type Rationale (2)

```
package MultiProcessor_Mutex is
   -- copying is prevented AND users cannot see contents
   type Spin_Lock is limited private;
   procedure Lock (The_Lock : in out Spin_Lock);
   procedure Unlock (The_Lock : in out Spin_Lock);
   pragma Inline (Lock, Unlock);
private
   type Spin_Lock is ...
end MultiProcessor_Mutex;
```

Limited Private Type Completions

- Clients have the partial view as `limited` and `private`
- The full view completion can be any kind of type
- Not required to be a record type just because the partial view is limited

```
package P is
   type Unique_ID_T is limited private;
   ...
private
   type Unique_ID_T is range 1 .. 10;
end P;
```

Write-Only Register Example

```
package Write_Only is
   type Byte is limited private;
   type Word is limited private;
   type Longword is limited private;
   procedure Assign (Input : in Unsigned_8;
                     To    : in out Byte);
   procedure Assign (Input : in Unsigned_16;
                     To    : in out Word);
   procedure Assign (Input : in Unsigned_32;
                     To    : in out Longword);
private
   type Byte is new Unsigned_8;
   type Word is new Unsigned_16;
   type Longword is new Unsigned_32;
end Write_Only;
```

Explicitly Limited Completions

- Completion in Full view includes word `limited`
- Optional
- Requires a record type as the completion

```
package MultiProcessor_Mutex is
   type Spin_Lock is limited private;
   procedure Lock (This : in out Spin_Lock);
   procedure Unlock (This : in out Spin_Lock);
private
   type Spin_Lock is limited -- full view is limited as well
      record
         Flag : Interfaces.Unsigned_8;
      end record;
end MultiProcessor_Mutex;
```

Effects of Explicitly Limited Completions

- Allows no internal copying too
- Forces parameters to be passed by-reference

```
package MultiProcessor_Mutex is
   type Spin_Lock is limited private;
   procedure Lock (This : in out Spin_Lock);
   procedure Unlock (This : in out Spin_Lock);
private
   type Spin_Lock is limited record
      Flag : Interfaces.Unsigned_8;
   end record;
end MultiProcessor_Mutex;
```

Automatically Limited Full View

- When other limited types are used in the representation
- Recall composite types containing limited types are `limited` too

```
package Foo is
   type Legal is limited private;
   type Also_Legal is limited private;
   type Not_Legal is private;
   type Also_Not_Legal is private;
private
   type Legal is record
      S : A_Limited_Type;
   end record;
   type Also_Legal is limited record
      S : A_Limited_Type;
   end record;
   type Not_Legal is limited record
      S : A_Limited_Type;
   end record;
   type Also_Not_Legal is record
      S : A_Limited_Type;
   end record;
end Foo;
```

Quiz

```
package P is
   type Priv is private;
private
   type Lim is limited null record;
   -- Complete Here
end P;
```

Which of the following piece(s) of code is(are) legal?

A.
```
type Priv is record
  E : Lim;
end record;
```

B.
```
type Priv is record
  E : Float;
end record;
```

C.
```
type A is array (1 .. 10) of Lim;
type Priv is record
  F : A;
end record;
```

D.
```
type Acc is access Lim;
type Priv is record
  F : Acc;
end record;
```

Quiz

```
package P is
   type Priv is private;
private
   type Lim is limited null record;
   -- Complete Here
end P;
```

Which of the following piece(s) of code is(are) legal?

A.
```
type Priv is record
  E : Lim;
end record;
```

B.
```
type Priv is record
  E : Float;
end record;
```

C.
```
type A is array (1 .. 10) of Lim;
type Priv is record
  F : A;
end record;
```

D.
```
type Acc is access Lim;
type Priv is record
  F : Acc;
end record;
```

A. `E` has limited type, partial view of `Priv` must be `private limited`

B. `F` has limited type, partial view of `Priv` must be `private limited`

Quiz

```
package P is
   type L1_T is limited private;
   type L2_T is limited private;
   type P1_T is private;
   type P2_T is private;
private
   type L1_T is limited record
      Field : Integer;
   end record;
   type L2_T is record
      Field : Integer;
   end record;
   type P1_T is limited record
      Field : L1_T;
   end record;
   type P2_T is record
      Field : L2_T;
   end record;
```

What will happen when the above code is compiled?

A. Type P1_T will generate a compile error
B. Type P2_T will generate a compile error
C. Both type P1_T and type P2_T will generate compile errors
D. The code will compile successfully

Quiz

```
package P is
   type L1_T is limited private;
   type L2_T is limited private;
   type P1_T is private;
   type P2_T is private;
private
   type L1_T is limited record
      Field : Integer;
   end record;
   type L2_T is record
      Field : Integer;
   end record;
   type P1_T is limited record
      Field : L1_T;
   end record;
   type P2_T is record
      Field : L2_T;
   end record;
```

What will happen when the above code is compiled?

A. ***Type P1_T will generate a compile error***
B. Type P2_T will generate a compile error
C. Both type P1_T and type P2_T will generate compile errors
D. The code will compile successfully

The full definition of type `P1_T` adds additional restrictions, which is not allowed. Although `P2_T` contains a component whose visible view is `limited`, the internal view is not `limited` so `P2_T` is not `limited`.

Lab

Limited Types Lab

- Requirements
  - Create an employee record data type consisting of a name, ID, hourly pay rate
    - ID should be unique for every record
  - Create a timecard record data type consisting of an employee record, hours worked, and total pay
  - Create a main program that generates timecards and prints their contents
- Hints
  - If the ID is unique, that means we cannot copy employee records

Limited Types Lab Solution - Employee Data (Spec)

```
with Ada.Strings.Unbounded; use Ada.Strings.Unbounded;
package Employee_Data is

  type Employee_T is limited private;
  type Hourly_Rate_T is delta 0.01 digits 6 range 0.0 .. 999.99;
  type Id_T is range 999 .. 9_999;

  function Create (Name : String;
                   Rate : Hourly_Rate_T := 0.0)
                   return Employee_T;
  function Id (Employee : Employee_T) return Id_T;
  function Name (Employee : Employee_T) return String;
  function Rate (Employee : Employee_T) return Hourly_Rate_T;

private
  type Employee_T is limited record
    Name : Unbounded_String := Null_Unbounded_String;
    Rate : Hourly_Rate_T    := 0.0;
    Id   : Id_T             := Id_T'First;
  end record;
end Employee_Data;
```

Limited Types Lab Solution - Timecards (Spec)

```
with Employee_Data;
package Timecards is

  type Hours_Worked_T is digits 3 range 0.0 .. 24.0;
  type Pay_T is digits 6;
  type Timecard_T is limited private;

  function Create (Name  : String;
                   Rate  : Employee_Data.Hourly_Rate_T;
                   Hours : Hours_Worked_T)
                   return Timecard_T;

  function Id (Timecard : Timecard_T) return Employee_Data.Id_T;
  function Name (Timecard : Timecard_T) return String;
  function Rate (Timecard : Timecard_T) return Employee_Data.Hourly_Rate_T;
  function Pay (Timecard : Timecard_T) return Pay_T;
  function Image ( Timecard : Timecard_T ) return String;

private
  type Timecard_T is limited record
    Employee     : Employee_Data.Employee_T;
    Hours_Worked : Hours_Worked_T := 0.0;
    Pay          : Pay_T          := 0.0;
  end record;
end Timecards;
```

Limited Types Lab Solution - Employee Data (Body)

```
package body Employee_Data is

  Last_Used_Id : Id_T := Id_T'First;

  function Create (Name : String;
                   Rate : Hourly_Rate_T := 0.0)
                   return Employee_T is
  begin
    return Ret_Val : Employee_T do
      Last_Used_Id := Id_T'Succ (Last_Used_Id);
      Ret_Val.Name := To_Unbounded_String (Name);
      Ret_Val.Rate := Rate;
      Ret_Val.Id   := Last_Used_Id;
    end return;
  end Create;

  function Id (Employee : Employee_T) return Id_T is (Employee.Id);
  function Name (Employee : Employee_T) return String is (To_String (Employee.Name));
  function Rate (Employee : Employee_T) return Hourly_Rate_T is (Employee.Rate);

end Employee_Data;
```

Limited Types Lab Solution - Timecards (Body)

```
package body Timecards is

  function Create (Name  : String;
                   Rate  : Employee_Data.Hourly_Rate_T;
                   Hours : Hours_Worked_T)
                   return Timecard_T is
  begin
    return (Employee     => Employee_Data.Create (Name, Rate),
            Hours_Worked => Hours,
            Pay          => Pay_T (Hours) * Pay_T (Rate));
  end Create;

  function Id (Timecard : Timecard_T) return Employee_Data.Id_T is
     (Employee_Data.Id (Timecard.Employee));
  function Name (Timecard : Timecard_T) return String is
     (Employee_Data.Name (Timecard.Employee));
  function Rate (Timecard : Timecard_T) return Employee_Data.Hourly_Rate_T is
     (Employee_Data.Rate (Timecard.Employee));
  function Pay (Timecard : Timecard_T) return Pay_T is
     (Timecard.Pay);

  function Image (Timecard : Timecard_T) return String is
    Name_S : constant String := Name (Timecard);
    Id_S   : constant String := Employee_Data.Id_T'Image (Employee_Data.Id (Timecard.Employee));
    Rate_S : constant String := Employee_Data.Hourly_Rate_T'Image
                                (Employee_Data.Rate (Timecard.Employee));
    Hours_S : constant String := Hours_Worked_T'Image (Timecard.Hours_Worked);
    Pay_S   : constant String := Pay_T'Image (Timecard.Pay);
  begin
    return Name_S & " ( " & Id_S & " ) => " & Hours_S & " hours * " & Rate_S & "/hour = " & Pay_S;
  end Image;
end Timecards;
```

Limited Types Lab Solution - Main

```
with Ada.Text_IO; use Ada.Text_IO;
with Timecards;
procedure Main is

   One : constant Timecards.Timecard_T :=
         Timecards.Create (Name  => "Fred Flintstone",
                           Rate  => 1.1,
                           Hours => 2.2);
   Two : constant Timecards.Timecard_T :=
         Timecards.Create (Name  => "Barney Rubble",
                           Rate  => 3.3,
                           Hours => 4.4);

begin
   Put_Line ( Timecards.Image ( One ) );
   Put_Line ( timecards.Image ( Two ) );
end Main;
```

Summary

Summary

- Limited view protects against improper operations
  - Incorrect equality semantics
  - Copying via assignment
- Enclosing composite types are `limited` too
  - Even if they don't use keyword `limited` themselves
- Limited types are always passed by-reference
- Extended return statements work for any type
  - Ada 2005 and later
- Don't make types `limited` unless necessary
  - Users generally expect assignment to be available

Genericity

Introduction

The Notion of a Pattern

- Sometimes algorithms can be abstracted from types and subprograms

```
procedure Swap_Int ( Left, Right : in out Integer) is
  V : Integer;
begin
   V := Left;
   Left := Right;
   Right := V;
end Swap_Int;

procedure Swap_Bool (Left, Right : in out Boolean) is
   V : Boolean;
begin
   V := Left;
   Left := Right;
   Right := V;
end Swap_Bool;
```

- It would be nice to extract these properties in some common pattern, and then just replace the parts that need to be replaced

```
-- T := Integer | Boolean
procedure Swap (Left, Right : in out T) is
  V : T;
begin
   V := Left;
   Left := Right;
   Right := V;
end Swap;
```

Solution: Generics

- A *generic unit* is a code pattern which can be reused
  - Does not get compiled as-is
- The instantiation applies the pattern to certain parameters
  - Based on properties
  - Use a *generic contract*
  - Parameters can be constant, variable, subprogram, type, package

Syntax

Usage

- Instantiated with the **new** keyword

```
--  Standard library
function Convert is new Ada.Unchecked_Conversion (Integer, A
--  Callbacks
procedure Parse_Tree is new Tree_Parser (Visitor_Procedure);
--  Containers, generic data-structures
package Integer_Stack is new Stack (Integer);
```

- Advanced usages for testing, proof, meta-programming

Declaration

- Subprograms

```
generic
   type T is private;
procedure Swap (L, R : in out T)
```

- Packages

```
generic
   type T is private;
package Stack is
   procedure Push (Item : T);
end Stack;
```

- Body is required
  - Will be specialized and compiled for **each instance**

Quiz

Which of the following statement is true?

A. Generics allow for code reuse
B. Generics can take packages as parameters
C. Genericity is specific to Ada
D. Genericity is available in all versions of Ada and/or SPARK

Quiz

Which of the following statement is true?

A. ***Generics allow for code reuse***
B. ***Generics can take packages as parameters***
C. Genericity is specific to Ada
D. ***Genericity is available in all versions of Ada and/or SPARK***

Quiz

Which one(s) of the following can be made generic?

```
generic
   type T is private;
<code goes here>
```

A. `package`
B. `record`
C. `function`
D. `array`

Quiz

Which one(s) of the following can be made generic?

```
generic
   type T is private;
<code goes here>
```

A. *package*
B. record
C. *function*
D. array

Only packages, functions, and procedures, can be made generic.

Quiz

Which of the following statement is true?

A. Generic instances must be nested inside a non-generic package
B. Generic instances must be created at compile-time
C. Generics instances can create new tagged types
D. Generics instances can create new tasks

Quiz

Which of the following statement is true?

A. Generic instances must be nested inside a non-generic package
B. Generic instances must be created at compile-time
C. ***Generics instances can create new tagged types***
D. ***Generics instances can create new tasks***

Generic instances can be created at any point, at a cost, and can do anything a package or subprogram can do, which make them versatile **but** potentially complex to use.

Generic Contracts

Examples

```
package Generic_Data is
   generic
      type Discrete_T is (<>);
      type Integer_T is range <>;
      type Float_T is digits <>;
      type Indefinite_T;
      type Tagged_T is tagged;
      type Array_T is array (Boolean) of Integer;
      type Access_T is access all Integer;
      type Private_T is private;
      type Unconstrained_T (<>) is private;
   package Parameter_Properties is
      procedure Do_Something ( Discrete_Param      : Discrete_T;
                               Integer_Param       : Integer_T;
                               Float_Param         : Float_T;
                               Indefinite_Param    : access Indefinite_T;
                               Tagged_Param        : Tagged_T;
                               Array_Param         : Array_T;
                               Access_Param        : Access_T;
                               Private_Param       : Private_T;
                               Unconstrained_Param : Unconstrained_T);
   end Parameter_Properties;

   generic
      type Item_T is private;
      type Access_Item_T is access all Item_T;
      type Index_T is (<>);
      type Array_T is array (Index_T range <>) of Access_Item_T;
   package Combination is
      procedure Add (List  : in out Array_T;
                     Index : in     Index_T;
                     Item  : in     Item_T);
   end Combination;
end Generic_Data;

with Types; use Types;
with Generic_Data;
package Generic_Instances is
   package Parameter_Properties_Instance is new Generic_Data
      .Parameter_Properties
     (Boolean, Integer, Float, Indefinite_T => Hidden_T,
      Tagged_T => Tagged_Record_T, Array_T => Boolean_Array_Of_Integers_T,
      Access_T => Access_Integer_T, Private_T => Some_Private_T,
      Unconstrained_T                         => String);

   type Item_T is (Red, White, Blue);
   type Access_T is access all Item_T;
   type Index_T is range 1 .. 100;
   type Array_T is array (Index_T range <>) of Access_T;
   package Combination_Instance is new Generic_Data.Combination
     (Item_T, Access_T, Index_T, Array_T);
end Generic_Instances;

package body Generic_Data is
   package body Parameter_Properties is
      procedure Do_Something ( Discrete_Param      : Discrete_T;
                               Integer_Param       : Integer_T;
                               Float_Param         : Float_T;
                               Indefinite_Param    : access Indefinite_T;
                               Tagged_Param        : Tagged_T;
                               Array_Param         : Array_T;
                               Access_Param        : Access_T;
                               Private_Param       : Private_T;
                               Unconstrained_Param : Unconstrained_T) is null;
   end Parameter_Properties;

   package body Combination is
      procedure Add (List  : in out Array_T;
                     Index : in     Index_T;
                     Item  : in     Item_T) is
      begin
         List (Index) := new Item_T'(Item);
      end Add;
   end Combination;
end Generic_Data;

package Types is
   type Hidden_T;
   type Tagged_Record_T is tagged record
      Field : access Hidden_T;
   end record;
   type Hidden_T is private;
   type Boolean_Array_Of_Integers_T is array (Boolean) of Integer;
   type Access_Integer_T is access all Integer;
   type Some_Private_T is private;
private
   type Hidden_T is new Integer;
   type Some_Private_T is new Integer;
end Types;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/SDD_genericity.html#generic-data

Definitions

- A formal generic parameter is a template
- Properties are either *constraints* or *capabilities*
  - Expressed from the **body** point of view
  - Constraints: e.g. unconstrained, `limited`
  - Capabilities: e.g. `tagged`, primitives

```
generic
   type Pv is private;             -- allocation, copy, assignment, "="
   with procedure Sort (T : Pv); -- primitive of Pv
   type Unc (<>) is private;       -- allocation require a value
   type Lim is limited private;  -- no copy or comparison
   type Disc is (<>);              -- 'First, ordering
package Generic_Pkg is [...]
```

- Actual parameter **may** require constraints, and **must** provide capabilities

```
package Pkg is new Generic_Pkg (
   Pv => Integer, -- has capabilities of private
   Sort => Sort -- procedure Sort (T : Integer)
   Unc => String,  -- uses "unconstrained" constraint
   Lim => Float,   -- does not use "limited" constraint
   Disc => Boolean, -- has capability of discrete
);
```

Syntax (partial)

```
type T1 is (<>); -- discrete
type T2 is range <>; -- integer
type T3 is digits <>; -- float
type T4 is private; -- indefinite
type T5 (<>) is private; -- indefinite
type T6 is tagged;
type T7 is array (Boolean) of Integer;
type T8 is access Integer;
type T9 is limited private;
```

- Not limited to those choices

```
type T is not null access all limited tagged private;
```

Quiz

Which of the following statement is true?

A. :Generics contracts define new types
B. Generic contracts can express any type constraint
C. Generic contracts can express inheritance constraint
D. Generic contracts can require a type to be numeric (Real or Integer)

Quiz

Which of the following statement is true?

A. :Generics contracts define new types
B. Generic contracts can express any type constraint
C. ***Generic contracts can express inheritance constraint***
D. Generic contracts can require a type to be numeric (Real or Integer)

A. No, the formal type and the actual type just have different views
B. Counter-example: representation clauses

Quiz

```
generic
   type T is tagged;
   type T2;
procedure G_P;

type Tag is tagged null record;
type Arr is array (Positive range <>) of Tag;
```

Which declaration(s) is(are) legal?

A. `procedure P is new G_P (Tag, Arr)`
B. `procedure P is new G_P (Arr, Tag)`
C. `procedure P is new G_P (Tag, Tag)`
D. `procedure P is new G_P (Arr, Arr)`

Quiz

```
generic
   type T is tagged;
   type T2;
procedure G_P;

type Tag is tagged null record;
type Arr is array (Positive range <>) of Tag;
```

Which declaration(s) is(are) legal?

A. *procedure P is new G_P (Tag, Arr)*
B. procedure P is new G_P (Arr, Tag)
C. *procedure P is new G_P (Tag, Tag)*
D. procedure P is new G_P (Arr, Arr)

Quiz

```
generic
   type T1 is (<>);
   type T2 (<>) is private;
procedure G
  (A : T1;
   B : T2);
```

Which is an illegal instantiation?

A. `procedure A is new G (String, Character);`
B. `procedure B is new G (Character, Integer);`
C. `procedure C is new G (Integer, Boolean);`
D. `procedure D is new G (Boolean, String);`

Quiz

```
generic
   type T1 is (<>);
   type T2 (<>) is private;
procedure G
  (A : T1;
   B : T2);
```

Which is an illegal instantiation?

A. `procedure A is new G (String, Character);`
B. `procedure B is new G (Character, Integer);`
C. `procedure C is new G (Integer, Boolean);`
D. `procedure D is new G (Boolean, String);`

T1 must be discrete - so an integer or an enumeration. T2 can be any type

Generic Formal Data

Examples

```
package Generic_Formal_Data is
   generic
      type Variable_T is range <>;
      Variable : in out Variable_T;
      Increment : Variable_T;
   package Constants_And_Variables is
      procedure Add;
      function Value return Variable_T is (Variable);
   end Constants_And_Variables;

   generic
      type Type_T is (<>);
      with procedure Print_One (Prompt : String; Value : Type_T);
      with procedure Print_Two (Prompt : String; Value : Type_T) is null;
      with procedure Print_Three (Prompt : String; Value : Type_T) is <>;
   package Subprogram_Parameters is
      procedure Print (Prompt : String; Param : Type_T);
   end Subprogram_Parameters;
end Generic_Formal_Data;

with Ada.Text_IO;         use Ada.Text_IO;
with Generic_Formal_Data; use Generic_Formal_Data;
procedure Test_Generic_Formal_Data is
   procedure Print_One (Prompt : String; Param : Integer) is
   begin
      Put_Line (Prompt & " - Print_One" & Param'Image);
   end Print_One;
   procedure Print_Two (Prompt : String; Param : Integer) is
   begin
      Put_Line (Prompt & " - Print_Two" & Param'Image);
   end Print_Two;
   procedure Print_Three (Prompt : String; Param : Integer) is
   begin
      Put_Line (Prompt & " - Print_Three" & Param'Image);
   end Print_Three;
   procedure Print_Three_Prime (Prompt : String; Param : Integer) is
   begin
      Put_Line (Prompt & " - Print_Three_Prime" & Param'Image);
   end Print_Three_Prime;

   Global_Object : Integer := 0;
   package Global_Data is new Constants_And_Variables
     (Integer, Global_Object, 111);

   package Print_1 is new Subprogram_Parameters (Integer, Print_One);
   package Print_2 is new Subprogram_Parameters (Integer, Print_One, Print_Two);
   package Print_3 is new Subprogram_Parameters (Integer, Print_One, Print_Two, Print_Three_Prime);

begin
   Print_1.Print ("print_1", Global_Data.Value);
   Global_Data.Add;
   Print_2.Print ("print_2", Global_Data.Value);
   Global_Data.Add;
   Print_3.Print ("print_3", Global_Data.Value);
end Test_Generic_Formal_Data;

package body Generic_Formal_Data is
   package body Constants_And_Variables is
      procedure Add is
      begin
         Variable := Variable + Increment;
      end Add;
   end Constants_And_Variables;

   package body Subprogram_Parameters is
      procedure Print (Prompt : String; Param : Type_T) is
      begin
         Print_One (Prompt, Param);
         Print_Two (Prompt, Param);
         Print_Three (Prompt, Param);
      end Print;
   end Subprogram_Parameters;
end Generic_Formal_Data;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/160_genericity.html#generic-formal-data

Generic Constants and Variables Parameters

- Variables can be specified on the generic contract
- The mode specifies the way the variable can be used:
  - `in` → read only
  - `in out` → read write
- Generic variables can be defined after generic types

```
generic
   type T is private;
   X1 : Integer;   -- constant
   X2 : in out T; -- variable
procedure P;

V : Float;

procedure P_I is new P
   (T  => Float,
    X1 => 42,
    X2 => V);
```

Generic Subprogram Parameters

- Subprograms can be defined in the generic contract
- Must be introduced by `with` to differ from the generic unit

```
generic
   with procedure Callback;
procedure P;
procedure P is
begin
   Callback;
end P;
procedure Something;
procedure P_I is new P (Something);
```

Quiz

```
generic
   type T is (<>);
   G_A : in out T;
procedure G_P;

type I is new Integer;
type E is (OK, NOK);
type F is new Float;
X : I;
Y : E;
Z : F;
```

Which of the following piece(s) of code is(are) legal?

A. `procedure P is new G_P (I, X)`
B. `procedure P is new G_P (E, Y)`
C. `procedure P is new G_P (I, E'Pos (Y))`
D. `procedure P is new G_P (F, Z)`

Quiz

```
generic
   type T is (<>);
   G_A : in out T;
procedure G_P;

type I is new Integer;
type E is (OK, NOK);
type F is new Float;
X : I;
Y : E;
Z : F;
```

Which of the following piece(s) of code is(are) legal?

A. *procedure P is new G_P (I, X)*
B. *procedure P is new G_P (E, Y)*
C. `procedure P is new G_P (I, E'Pos (Y))`
D. `procedure P is new G_P (F, Z)`

Quiz

```
generic
   type L is limited private;
   type P is private;
procedure G_P;

type Lim is limited null record;
type Int is new Integer;

type Rec is record
   L : Lim;
   I : Int;
end record;
```

Which declaration(s) is(are) legal?

A. `procedure P is new G_P (Lim, Int)`
B. `procedure P is new G_P (Int, Rec)`
C. `procedure P is new G_P (Rec, Rec)`
D. `procedure P is new G_P (Int, Int)`

Quiz

```
generic
   type L is limited private;
   type P is private;
procedure G_P;

type Lim is limited null record;
type Int is new Integer;

type Rec is record
   L : Lim;
   I : Int;
end record;
```

Which declaration(s) is(are) legal?

A. *procedure P is new G_P (Lim, Int)*
B. procedure P is new G_P (Int, Rec)
C. procedure P is new G_P (Rec, Rec)
D. *procedure P is new G_P (Int, Int)*

Summary

Summary

- Generics are useful for **reusing code**
  - Sorting, containers, etc
- Generic contracts syntax is different from Ada declaration
  - But has some resemblance to it
  - e.g. discretes' `type Enum is (A, B, C)` vs generics' `type T is (<>)`
- Instanciation "generates" code
  - Costly
  - Beware of local generic instances!

Exceptions

Introduction

Rationale for Exceptions

- Textual separation from normal processing
- Rigorous Error Management
  - Cannot be ignored, unlike status codes from routines
  - Example: running out of gasoline in an automobile

```
package Automotive is
  type Vehicle is record
    Fuel_Quantity, Fuel_Minimum : Float;
    Oil_Temperature : Float;
    ...
  end record;
  Fuel_Exhausted : exception;
  procedure Consume_Fuel (Car : in out Vehicle);
  ...
end Automotive;
```

Semantics Overview

- Exceptions become active by being *raised*
  - Failure of implicit language-defined checks
  - Explicitly by application
- Exceptions occur at run-time
  - A program has no effect until executed
- May be several occurrences active at same time
  - One per thread of control
- Normal execution abandoned when they occur
  - Error processing takes over in response
  - Response specified by *exception handlers*
  - *Handling the exception* means taking action in response
  - Other threads need not be affected

Semantics Example: Raising

```
package body Automotive is
   function Current_Consumption return Float is
      ...
   end Current_Consumption;
   procedure Consume_Fuel (Car : in out Vehicle) is
   begin
      if Car.Fuel_Quantity <= Car.Fuel_Minimum then
         raise Fuel_Exhausted;
      else -- decrement quantity
         Car.Fuel_Quantity := Car.Fuel_Quantity -
                              Current_Consumption;
      end if;
   end Consume_Fuel;
   ...
end Automotive;
```

Semantics Example: Handling

```
procedure Joy_Ride is
   Hot_Rod : Automotive.Vehicle;
   Bored : Boolean := False;
   use Automotive;
begin
   while not Bored loop
      Steer_Aimlessly (Bored);
      -- error situation cannot be ignored
      Consume_Fuel (Hot_Rod);
   end loop;
   Drive_Home;
exception
   when Fuel_Exhausted =>
      Push_Home;
end Joy_Ride;
```

Handler Part Is Skipped Automatically

- If no exceptions are active, returns normally

```
begin
   ...
-- if we get here, skip to end
exception
   when Name1 =>
   ...
   when Name2 | Name3 =>
   ...
   when Name4 =>
   ...
end;
```

Handlers

Examples

```
with Ada.Text_IO; use Ada.Text_IO;
with Automotive;  use Automotive;
procedure Joy_Ride is
   Hot_Rod : Vehicle_T;
   Bored   : Boolean := False;
begin
   while not Bored loop
      Steer_Aimlessly (Bored);
      Consume_Fuel (Hot_Rod);
   end loop;
   Put_Line ("Driving Home");
   Drive_Home;
exception
   when Fuel_Exhausted =>
      Put_Line ("Pushing Home");
      Push_Home;
end Joy_Ride;

package Automotive is
   Fuel_Exhausted : exception;

   type Vehicle_T is record
      Fuel_Quantity : Float := 10.0;
      Fuel_Minimum  : Float := 1.0;
   end record;

   procedure Consume_Fuel (Car : in out Vehicle_T);
   procedure Steer_Aimlessly (Flag : out Boolean);
   procedure Drive_Home;
   procedure Push_Home;
end Automotive;

with GNAT.Random_Numbers; use GNAT.Random_Numbers;
package body Automotive is
   Gen : Generator;
   function Current_Consumption is new Random_Float (Float);
   function Random_Number is new Random_Discrete (Integer);

   procedure Consume_Fuel (Car : in out Vehicle_T) is
   begin
      if Car.Fuel_Quantity <= Car.Fuel_Minimum then
         raise Fuel_Exhausted;
      else
         Car.Fuel_Quantity := Car.Fuel_Quantity - Current_Consumption (Gen);
      end if;
   end Consume_Fuel;

   procedure Steer_Aimlessly (Flag : out Boolean) is
   begin
      Flag := Random_Number (Gen, 1, 50) = 1;
      if Random_Number (Gen, 1, 50) = 2 then
         raise Constraint_Error;
      end if;
   end Steer_Aimlessly;

   procedure Drive_Home is null;
   procedure Push_Home is null;

begin
   Reset (Gen);
end Automotive;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/190_exceptions.html#handlers

Exception Handler Part

- Contains the exception handlers within a frame
  - Within block statements, subprograms, tasks, etc.
- Separates normal processing code from abnormal
- Starts with the reserved word `exception`
- Optional

```
begin
   sequence_of_statements
[ exception
     exception_handler
     { exception handler } ]
end
```

Exception Handlers Syntax

- Associates exception names with statements to execute in response
- If used, **others** must appear at the end, by itself
  - Associates statements with all other exceptions
- Syntax

```
exception_handler ::=
  when exception_choice { | exception_choice } =>
    sequence_of_statements
exception_choice ::= exception_name | others
```

Similarity To Case Statements

- Both structure and meaning
- Exception handler

```
...
exception
  when Constraint_Error | Storage_Error | Program_Error =>
  ...
  when others =>
  ...
end;
```

- Case statement

```
case exception_name is
  when Constraint_Error | Storage_Error | Program_Error =>
  ...
  when others =>
  ...
end case;
```

Handlers Don't "Fall Through"

```
begin
   ...
   raise Name3;
   -- code here is not executed
   ...
exception
   when Name1 =>
      -- not executed
      ...
   when Name2 | Name3 =>
      -- executed
      ...
   when Name4 =>
      -- not executed
      ...
end;
```

When An Exception Is Raised

- Normal processing is abandoned
- Handler for active exception is executed, if any
- Control then goes to the caller
- If handled, caller continues normally, otherwise repeats the above

- Caller

```
...
Joy_Ride;
Do_Something_At_Home;
...
```

- Callee

```
procedure Joy_Ride is
   ...
begin
   ...
   Drive_Home;
exception
   when Fuel_Exhausted =>
      Push_Home;
end Joy_Ride;
```

Handling Specific Statements' Exceptions

```
begin
   loop
      Prompting : loop
         Put (Prompt);
         Get_Line (Filename, Last);
         exit when Last > Filename'First - 1;
      end loop Prompting;
      begin
         Open (F, In_File, Filename (1..Last));
         exit;
      exception
         when Name_Error =>
            Put_Line ("File '" & Filename (1..Last) &
                      "' was not found.");
      end;
   end loop;
```

Exception Handler Content

- No restrictions
  - Block statements, subprogram calls, etc.
- Do whatever makes sense

```
begin
   ...
exception
   when Some_Error =>
      declare
         New_Data : Some_Type;
      begin
         P (New_Data);
         ...
      end;
end;
```

Quiz

```
1  procedure Main is
2     A, B, C, D : Integer range 0 .. 100;
3  begin
4     A := 1; B := 2; C := 3; D := 4;
5     begin
6        D := A - C + B;
7     exception
8        when others => Put_Line ("One");
9                       D := 1;
10    end;
11    D := D + 1;
12    begin
13       D := D / (A - C + B);
14    exception
15       when others => Put_Line ("Two");
16                      D := -1;
17    end;
18 exception
19    when others =>
20       Put_Line ("Three");
21 end Main;
```

What will get printed?

A. One, Two, Three
B. Two, Three
C. Two
D. Three

Quiz

```
1  procedure Main is
2     A, B, C, D : Integer range 0 .. 100;
3  begin
4     A := 1; B := 2; C := 3; D := 4;
5     begin
6        D := A - C + B;
7     exception
8        when others => Put_Line ("One");
9                       D := 1;
10    end;
11    D := D + 1;
12    begin
13       D := D / (A - C + B);
14    exception
15       when others => Put_Line ("Two");
16                      D := -1;
17    end;
18 exception
19    when others =>
20       Put_Line ("Three");
21 end Main;
```

What will get printed?

A. One, Two, Three
B. ***Two, Three***
C. Two
D. Three

Explanations

A. Although `(A - C)` is not in the range of `natural`, the range is only checked on assignment, which is after the addition of `B`, so `One` is never printed
B. Correct
C. If we reach `Two`, the assignment on line 10 will cause `Three` to be reached
D. Divide by 0 on line 14 causes an exception, so `Two` must be called

Implicitly and Explicitly Raised Exceptions

Examples

```
with Ada.Text_IO; use Ada.Text_IO;
package body Implicit_Exceptions is
   Array_Object : array (1 .. 100) of Integer;

   procedure Raise_Constraint_Error (X : Integer) is
   begin
      Put_Line ("* Raise_Constraint_Error: " & X'Image);
      Array_Object (X) := X - 10;
   end Raise_Constraint_Error;

   function Raise_Program_Error (X : Integer) return Boolean is
   begin
      Put_Line ("* Raise_Program_Error: " & X'Image);
      if X in Array_Object'Range then
         return Array_Object (X) > 0;
      end if;
   end Raise_Program_Error;
end Implicit_Exceptions;

with Ada.Text_IO; use Ada.Text_IO;
package body Explicit_Exceptions is
   procedure Raise_Storage_Error (X : Integer) is
   begin
      Put_Line ("* Raise_Storage_Error: " & X'Image);
      if X < 0 then
         raise Storage_Error;
      end if;
   end Raise_Storage_Error;
end Explicit_Exceptions;

with Ada.Text_IO;          use Ada.Text_IO;
with Implicit_Exceptions; use Implicit_Exceptions;
with Explicit_Exceptions; use Explicit_Exceptions;
procedure Test_Exceptions is
   procedure Test_Constraint_Error (X : Integer) is
   begin
      Raise_Constraint_Error (X);
      Put_Line ("Test_Constraint_Error success");
   exception
      when Constraint_Error =>
         Put_Line ("Test_Constraint_Error caught exception");
   end Test_Constraint_Error;

   procedure Test_Program_Error (X : Integer) is
   begin
      if Raise_Program_Error (X) then
         Put_Line ("Test_Program_Error true");
      else
         Put_Line ("Test_Program_Error false");
      end if;
   exception
      when Program_Error =>
         Put_Line ("Test_Program_Error caught exception");
   end Test_Program_Error;

   procedure Test_Storage_Error (X : Integer) is
   begin
      Raise_Storage_Error (X);
      Put_Line ("Test_Storage_Error success");
   exception
      when Storage_Error =>
         Put_Line ("Test_Storage_Error caught exception");
   end Test_Storage_Error;

begin
   Test_Constraint_Error (20);
   Test_Constraint_Error (0);
   Test_Constraint_Error (Integer'Last);
   Test_Program_Error (Integer'First);
   Test_Program_Error (Integer'Last);
   Test_Storage_Error (Integer'First);
   Test_Storage_Error (Integer'Last);
end Test_Exceptions;

package Implicit_Exceptions is
   procedure Raise_Constraint_Error (X : Integer);
   function Raise_Program_Error (X : Integer) return Boolean;
end Implicit_Exceptions;

package Explicit_Exceptions is
   procedure Raise_Storage_Error (X : Integer);
end Explicit_Exceptions;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/100_exceptions.html#implicitly-and-explicitly-raised-exceptions

Implicitly-Raised Exceptions

- Correspond to language-defined checks
- Can happen by statement execution

```
K := -10;   -- where K must be greater than zero
```

- Can happen by declaration elaboration

```
Doomed : array (Positive) of Big_Type;
```

Some Language-Defined Exceptions

- `Constraint_Error`
  - Violations of constraints on range, index, etc.
- `Program_Error`
  - Runtime control structure violated (function with no return ...)
- `Storage_Error`
  - Insufficient storage is available
- For a complete list see RM Q-4

Explicitly-Raised Exceptions

- Raised by application via `raise` statements
  - Named exception becomes active
- Syntax

```
raise_statement ::= raise; |
   raise exception_name
   [with string_expression];
```

  - `with string_expression` only available in Ada 2005 and later
- A `raise` by itself is only allowed in handlers

```
if Unknown (User_ID) then
  raise Invalid_User;
end if;
```

```
if Unknown (User_ID) then
  raise Invalid_User
     with "Attempt by " &
          Image (User_ID);
end if;
```

User-Defined Exceptions

Examples

```
package Stack is
   Underflow, Overflow : exception;
   procedure Push (Item : in Integer);
   procedure Pop (Item : out Integer);
end Stack;

package body Stack is
   Values : array (1 .. 100) of Integer;
   Top    : Integer := 0;

   procedure Push (Item : in Integer) is
   begin
      if Top = Values'Last then
         raise Overflow;
      end if;
      Top           := Top + 1;
      Values (Top) := Item;
   end Push;

   procedure Pop (Item : out Integer) is
   begin
      if Top < Values'First then
         raise Underflow;
      end if;
      Item := Values (Top);
      Top  := Top - 1;
   end Pop;
end Stack;

with Ada.Text_IO; use Ada.Text_IO;
with Stack;
procedure Test_Stack is
   Global : Integer := 123;

   procedure Push (X : Integer) is
   begin
      Stack.Push (X);
   exception
      when Stack.Overflow =>
         Put_Line ("No room on the stack");
   end Push;

   procedure Pop is
   begin
      Stack.Pop (Global);
   exception
      when Stack.Underflow =>
         Put_Line ("Nothing on the stack");
   end Pop;

begin
   Pop;
   for I in 1 .. 100 loop
      Push (I);
   end loop;
   Push (2);
end Test_Stack;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/190_exceptions.html#user-defined-exceptions

User-Defined Exceptions

- Syntax

```
defining_identifier_list : exception;
```

- Behave like predefined exceptions
  - Scope and visibility rules apply
  - Referencing as usual
  - Some minor differences
- Exception identifiers' use is restricted
  - `raise` statements
  - Handlers
  - Renaming declarations

User-Defined Exceptions Example

- An important part of the abstraction
- Designer specifies how component can be used

```
package Stack is
  Underflow, Overflow : exception;
  procedure Push (Item : in Integer);
  ...
end Stack;

package body Stack is
  procedure Push (Item : in Integer) is
  begin
    if Top = Index'Last then
      raise Overflow;
    end if;
    Top := Top + 1;
    Values (Top) := Item;
  end Push;
...
```

Propagation

Examples

```
with Ada.Text_IO;         use Ada.Text_IO;
with GNAT.Random_Numbers; use GNAT.Random_Numbers;
procedure Propagation is
   Error1 : exception;
   Error2 : exception;

   Gen : Generator;
   procedure Maybe_Raise is
      Test : constant Float := Random (Gen);
   begin
      if Test > 0.666 then
         raise Error1;
      end if;
   exception
      when Error1 =>
         if Test > 0.95 then
            raise Error2;
         else
            raise;
         end if;
   end Maybe_Raise;

   procedure One is
   begin
      Maybe_Raise;
   end One;

   procedure Two is
   begin
      One;
      Maybe_Raise;
   exception
      when Error1 =>
         Put_Line ("Exception from 1 or 2");
   end Two;

begin
   Reset (Gen);
   Maybe_Raise;
   Two;
exception
   when Error1 =>
      Put_Line ("Exception from 3");
end Propagation;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/190_exceptions.html#propagation

Propagation

- Control does not return to point of raising
  - Termination Model
- When a handler is not found in a block statement
  - Re-raised immediately after the block
- When a handler is not found in a subprogram
  - Propagated to caller at the point of call
- Propagation is dynamic, back up the call chain
  - Not based on textual layout or order of declarations
- Propagation stops at the main subprogram
  - Main completes abnormally unless handled

Propagation Demo

```
1  procedure Do_Something is
2    Error : exception;
3    procedure Unhandled is
4    begin
5      Maybe_Raise(1);
6    end Unhandled;
7    procedure Handled is
8    begin
9      R;
10     Maybe_Raise(2);
11   exception
12     when Error =>
13       Print("Handle 1 or 2");
14   end Handled;
```

```
16 begin -- Do_Something
17   Maybe_Raise(3);
18   Handled;
19 exception
20   when Error =>
21     Print("Handle 3");
22 end Do_Something;
```

Termination Model

- When control goes to handler, it continues from here

```
procedure Joy_Ride is
begin
   loop
       Steer_Aimlessly;

       -- If next line raises Fuel_Exhausted, go to handler
       Consume_Fuel;
   end loop;
exception
  when Fuel_Exhausted => -- Handler
    Push_Home;
    -- Resume from here: loop has been exited
end Joy_Ride;
```

Quiz

```
2  Main_Problem : exception;
3  I : Integer;
4  function F (P : Integer) return Integer is
5  begin
6    if P > 0 then
7      return P + 1;
8    elsif P = 0 then
9      raise Main_Problem;
10   end if;
11 end F;
12 begin
13   I := F(Input_Value);
14   Put_Line ("Success");
15 exception
16   when Constraint_Error => Put_Line ("Constraint Error");
17   when Program_Error    => Put_Line ("Program Error");
18   when others           => Put_Line ("Unknown problem");
```

What will get printed if `Input_Value` on line 19 is `Integer'Last`?

A. `Unknown Problem`
B. `Success`
C. `Constraint Error`
D. `Program Error`

Quiz

```
2  Main_Problem : exception;
3  I : Integer;
4  function F (P : Integer) return Integer is
5  begin
6    if P > 0 then
7      return P + 1;
8    elsif P = 0 then
9      raise Main_Problem;
10   end if;
11 end F;
12 begin
13   I := F(Input_Value);
14   Put_Line ("Success");
15 exception
16   when Constraint_Error => Put_Line ("Constraint Error");
17   when Program_Error    => Put_Line ("Program Error");
18   when others           => Put_Line ("Unknown problem");
```

What will get printed if `Input_Value` on line 19 is `Integer'Last`?

A. `Unknown Problem`
B. `Success`
C. *`Constraint Error`*
D. `Program Error`

Explanations

A. `"Unknown problem"` is printed by the **`when others`** due to the raise on line 8 when `P` is 0
B. `"Success"` is printed when $0 < P < \texttt{Integer'Last}$
C. Trying to add 1 to `P` on line 7 generates a `Constraint_Error`
D. `Program_Error` will be raised by `F` if $P < 0$ (no **`return`** statement found)

Exceptions as Objects

Examples

```
package Exception_Objects_Example is

   Public_Exception : exception;

   procedure Do_Something (X : Integer);

end Exception_Objects_Example;

package body Exception_Objects_Example is
   Hidden_Exception : exception;

   procedure Do_Something (X : Integer) is
   begin
      if X < 0 then
         raise Public_Exception;
      elsif X = 0 then
         raise Hidden_Exception;
      end if;
   end Do_Something;

end Exception_Objects_Example;

with Ada.Exceptions;            use Ada.Exceptions;
with Ada.Text_IO;               use Ada.Text_IO;
with Exception_Objects_Example; use Exception_Objects_Example;
procedure Test_Exception_Objects_Example is
begin

   for I in -1 .. 1 loop
      begin
         Put_Line ("Try " & I'Image);
         Do_Something (I);
         Put_Line ("   success");
      exception
         when Public_Exception =>
            Put_Line ("   Expected exception");
         when The_Err : others =>
            Put_Line ("   Unexpected exception");
            Put_Line ("      Name: " & Exception_Name (The_Err));
            Put_Line ("      Information: " & Exception_Information (The_Err));
            Put_Line ("      Message: " & Exception_Message (The_Err));
      end;
   end loop;

end Test_Exception_Objects_Example;
```

https://learn.adacore.com/training_examples/fundamentals_of_ada/190_exceptions.html#exceptions-as-objects

Exceptions Are Not Objects

- May not be manipulated
  - May not be components of composite types
  - May not be passed as parameters
- Some differences for scope and visibility
  - May be propagated out of scope

But You Can Treat Them As Objects

- For raising and handling, and more
- Standard Library

```
package Ada.Exceptions is
  type Exception_Id is private;
  procedure Raise_Exception (E : Exception_Id;
                             Message : String := "");
  ...
  type Exception_Occurrence is limited private;
  function Exception_Name (X : Exception_Occurrence)
      return String;
  function Exception_Message (X : Exception_Occurrence)
      return String;
  function Exception_Information (X : Exception_Occurrence)
      return String;
  procedure Reraise_Occurrence (X : Exception_Occurrence);
  procedure Save_Occurrence (
    Target : out Exception_Occurrence;
    Source : Exception_Occurrence);
  ...
end Ada.Exceptions;
```

Exception Occurence

- Syntax associates an object with active exception

```
when defining_identifier : exception_name ... =>
```

- A constant view representing active exception
- Used with operations defined for the type

```
exception
  when Catched_Exception : others =>
    Put (Exception_Name (Catched_Exception));
```

Exception_Occurrence Query Functions

- **Exception_Name**
  - Returns full expanded name of the exception in string form
    - Simple short name if space-constrained
  - Predefined exceptions appear as just simple short name
- **Exception_Message**
  - Returns string value specified when raised, if any
- **Exception_Information**
  - Returns implementation-defined string content
  - Should include both exception name and message content
  - Presumably includes debugging information
    - Location where exception occurred
    - Language-defined check that failed (if such)

Exception ID

- For an exception identifier, the *identity* of the exception is `<name>'Identity`

```
Mine : exception
use Ada.Exceptions;
...
exception
   when Occurrence : others =>
      if Exception_Identity(Occurrence) = Mine'Identity
      then
         ...
```

Raise Expressions

Raise Expressions

Ada 2012

- **Expression** raising specified exception **at run-time**

```
Foo : constant Integer := ( case X is
                              when 1 => 10,
                              when 2 => 20,
                              when others => raise Error);
```

In Practice

Exceptions Are Not Always Appropriate

- What does it mean to have an unexpected error in a safety-critical application?
  - Maybe there's no reasonable response

Relying On Exception Raising Is Risky

- They may be **suppressed**
- Not recommended

```
function Tomorrow (Today : Days) return Days is
begin
  return Days'Succ (Today);
exception
  when Constraint_Error =>
    return Days'First;
end Tomorrow;
```

- Recommended

```
function Tomorrow (Today : Days) return Days is
begin
  if Today = Days'Last then
    return Days'First;
  else
    return Days'Succ (Today);
  end if;
end Tomorrow;
```

Lab

Exceptions Lab

(Simplified) Input Verifier

- Overview
  - Create an application that allows users to enter integer values
- Goal
  - Application should read data from a string and return the numeric value (or raise an exception)

Project Requirements

- Exception Tracking
  - Non-numeric data should raise a different exception than out-of-range data
  - Exceptions should not stop the application
- Extra Credit
  - Handle values with exponents (e.g 123E4)

Exceptions Lab Solution - Types

```
package Types is

   Max_Int : constant := 2**15;
   type Integer_T is range -(Max_Int) .. Max_Int - 1;

end Types;
```

Exceptions Lab Solution - Converter

```
with Types;
package Converter is
   Illegal_String : exception;
   Out_Of_Range   : exception;
   function Convert (Str : String) return Types.Integer_T;
end Converter;

package body Converter is

   function Legal (C : Character) return Boolean is
   begin
      return
        C in '0' .. '9' or C = '+' or C = '-' or C = '+' or C = '_' or
        C = 'e' or C = 'E';
   end Legal;

   function Convert (Str : String) return Types.Integer_T is
   begin
      for I in Str'range loop
         if not Legal (Str (I)) then
            raise Illegal_String;
         end if;
      end loop;
      return Types.Integer_T'value (Str);
   exception
      when Constraint_Error =>
         raise Out_Of_Range;
   end Convert;

end Converter;
```

Exceptions Lab Solution - Main

```
with Ada.Text_IO;
with Converter;
with Types;
procedure Main is

   procedure Print_Value (Str : String) is
      Value : Types.Integer_T;
   begin
      Ada.Text_IO.Put (Str & " => ");
      Value := Converter.Convert (Str);
      Ada.Text_IO.Put_Line (Types.Integer_T'image (Value));
   exception
      when Converter.Out_Of_Range =>
         Ada.Text_IO.Put_Line ("Out of range");
      when Converter.Illegal_String =>
         Ada.Text_IO.Put_Line ("Illegal entry");
   end Print_Value;

begin
   Print_Value ("123");
   Print_Value ("2_3_4");
   Print_Value ("-345");
   Print_Value ("+456");
   Print_Value ("1234567890");
   Print_Value ("123abc");
   Print_Value ("12e3");
end Main;
```

Summary

Summary

- Should be for unexpected errors
- Give clients the ability to avoid them
- If handled, caller should see normal effect
  - Mode `out` parameters assigned
  - Function return values provided
- Package **Ada.Exceptions** provides views as objects
  - For both raising and special handling
  - Especially useful for debugging
- Checks may be suppressed

Interfacing with C

Introduction

Introduction

- Lots of C code out there already
  - Maybe even a lot of reusable code in your own repositories
- Need a way to interface Ada code with existing C libraries
  - Built-in mechanism to define ability to import objects from C or export Ada objects
- Passing data between languages can cause issues
  - Sizing requirements
  - Passing mechanisms (by reference, by copy)

Import / Export

Pragma Import / Export (1/2)

- `Pragma Import` allows a C implementation to complete an Ada specification
  - Ada view

```
procedure C_Proc;
pragma Import (C, C_Proc, "SomeProcedure");
```

  - C implementation

```
void SomeProcedure (void) {
   // some code
}
```

- `Pragma Export` allows an Ada implementation to complete a C specification
  - Ada implementation

```
procedure Some_Procedure;
pragma Export (C, SomeProcedure, "ada_some_procedure");
procedure Some_Procedure is
begin
 -- some code
end Some_Procedure;
```

  - C view

```
extern void ada_some_procedure (void);
```

Pragma Import / Export (2/2)

- You can also import/export variables
  - Variables imported won't be initialized
  - Ada view

```
My_Var : integer_type;
Pragma Import ( C, My_Var, "my_var" );
```

  - C implementation

```
int my_var;
```

Import / Export in Ada 2012

Ada 2012

- In Ada 2012, `Import` and `Export` can also be done using aspects:

```
procedure C_Proc
  with Import,
       Convention    => C,
       External_Name => "c_proc";
```

Parameter Passing

Parameter Passing to/from C

- The mechanism used to pass formal subprogram parameters and function results depends on:
  - The type of the parameter
  - The mode of the parameter
  - The Convention applied on the Ada side of the subprogram declaration.
- The exact meaning of *Convention C*, for example, is documented in *LRM* B.1 - B.3, and in the *GNAT User's Guide* section 3.11.

Passing Scalar Data as Parameters

- C types are defined by the Standard
- Ada types are implementation-defined
- GNAT standard types are compatible with C types
  - Implementation choice, use carefully.
- At the interface level, scalar types must be either constrained with representation clauses, or coming from Interfaces.C
- Ada view

```
with Interfaces.C;
function C_Proc (I : Interfaces.C.Int)
    return Interfaces.C.Int;
pragma Import (C, C_Proc, "c_proc");
```

- C view

```
int c_proc (int i) {
  /* some code */
}
```

Passing Structures as Parameters

- An Ada record that is mapping on a C struct must:
  - Be marked as convention C to enforce a C-like memory layout
  - Contain only C-compatible types
- C View

```
enum Enum {E1, E2, E3};
struct Rec {
   int A, B;
   Enum C;
};
```

- Ada View

```
type Enum is (E1, E2, E3);
Pragma Convention ( C, Enum );
type Rec is record
  A, B : int;
  C : Enum;
end record;
Pragma Convention ( C, Rec );
```

- Using Ada 2012 aspects

```
type Enum is (E1, E2, E3) with Convention => C;
type Rec is record
  A, B : int;
  C : Enum;
end record with Convention => C;
```

Parameter modes

- `in` scalar parameters passed by copy
- `out` and `in out` scalars passed using temporary pointer on C side
- By default, composite types passed by reference on all modes except when the type is marked `C_Pass_By_Copy`
  - Be very careful with records - some C ABI pass small structures by copy!
- Ada View

```
Type R1 is record
   V : int;
end record
with Convention => C;

type R2 is record
   V : int;
end record
with Convention => C_Pass_By_Copy;
```

- C View

```
struct R1{
   int V;
};
struct R2 {
   int V;
};
void f1 (R1 p);
void f2 (R2 p);
```

Complex Data Types

Unions

- C `union`

```
union Rec {
   int A;
   float B;
};
```

- C unions can be bound using the `Unchecked_Union` aspect
- These types must have a mutable discriminant for convention purpose, which doesn't exist at run-time
  - All checks based on its value are removed - safety loss
  - It cannot be manually accessed
- Ada implementation of a C `union`

```
type Rec (Flag : Boolean := False) is
record
   case Flag is
      when True =>
         A : int;
      when False =>
         B : float;
   end case;
end record
with Unchecked_Union,
     Convention => C;
```

Arrays Interfacing

- In Ada, arrays are of two kinds:
  - Constrained arrays
  - Unconstrained arrays
- Unconstrained arrays are associated with
  - Components
  - Bounds
- In C, an array is just a memory location pointing (hopefully) to a structured memory location
  - C does not have the notion of unconstrained arrays
- Bounds must be managed manually
  - By convention (null at the end of string)
  - By storing them on the side
- Only Ada constrained arrays can be interfaced with C

Arrays from Ada to C

- An Ada array is a composite data structure containing 2 elements: Bounds and Elements
  - **Fat pointers**
- When arrays can be sent from Ada to C, C will only receive an access to the elements of the array
- Ada View

```
type Arr is array (Integer range <>) of int;
procedure P (V : Arr; Size : int);
pragma Import (C, P, "p");
```

- C View

```
void p (int * v, int size)  {
}
```

Arrays from C to Ada

- There are no boundaries to C types, the only Ada arrays that can be bound must have static bounds
- Additional information will probably need to be passed
- Ada View

```
-- DO NOT DECLARE OBJECTS OF THIS TYPE
type Arr is array (0 .. Integer'Last) of int;

procedure P (V : Arr; Size : int);
pragma Export (C, P, "p");

procedure P (V : Arr; Size : int) is
begin
   for J in 0 .. Size - 1 loop
      -- code;
   end loop;
end P;
```

- C View

```
extern void p (int * v, int size);
int x [100];
p (x, 100);
```

Strings

- Importing a `String` from C is like importing an array - has to be done through a constrained array
- `Interfaces.C.Strings` gives a standard way of doing that
- Unfortunately, C strings have to end by a null character
- Exporting an Ada string to C needs a copy!

```
Ada_Str : String := "Hello World";
C_Str : chars_ptr := New_String (Ada_Str);
```

- Alternatively, a knowledgeable Ada programmer can manually create Ada strings with correct ending and manage them directly

```
Ada_Str : String := "Hello World" & ASCII.NUL;
```

- Back to the unsafe world - it really has to be worth it speed-wise!

Interfaces.C

Interfaces.C Hierarchy

- Ada supplies a subsystem to deal with Ada/C interactions
- `Interfaces.C` - contains typical C types and constants, plus some simple Ada string to/from C character array conversion routines
  - `Interfaces.C.Extensions` - some additonal C/C++ types
  - `Interfaces.C.Pointers` - generic package to simulate C pointers (pointer as an unconstrained array, pointer arithmetic, etc)
  - `Interfaces.C.Strings` - types / functions to deal with C "char *"

Interfaces.C

```
package Interfaces.C is

   --  Declaration's based on C's <limits.h>
   CHAR_BIT  : constant := 8;
   SCHAR_MIN : constant := -128;
   SCHAR_MAX : constant := 127;
   UCHAR_MAX : constant := 255;

   type int   is new Integer;
   type short is new Short_Integer;
   type long  is range -(2 ** (System.Parameters.long_bits - Integer'(1)))
     .. +(2 ** (System.Parameters.long_bits - Integer'(1))) - 1;

   type signed_char is range SCHAR_MIN .. SCHAR_MAX;
   for signed_char'Size use CHAR_BIT;

   type unsigned       is mod 2 ** int'Size;
   type unsigned_short is mod 2 ** short'Size;
   type unsigned_long  is mod 2 ** long'Size;

   type unsigned_char is mod (UCHAR_MAX + 1);
   for unsigned_char'Size use CHAR_BIT;

   type ptrdiff_t is range -(2 ** (System.Parameters.ptr_bits - Integer'(1))) ..
                           +(2 ** (System.Parameters.ptr_bits - Integer'(1)) - 1);

   type size_t is mod 2 ** System.Parameters.ptr_bits;

   --  Floating-Point
   type C_float     is new Float;
   type double      is new Standard.Long_Float;
   type long_double is new Standard.Long_Long_Float;

   type char is new Character;
   nul : constant char := char'First;

   function To_C   (Item : Character) return char;
   function To_Ada (Item : char)      return Character;

   type char_array is array (size_t range <>) of aliased char;
   for char_array'Component_Size use CHAR_BIT;

   function Is_Nul_Terminated (Item : char_array) return Boolean;

   -- (more not specified here)

end Interfaces.C;
```

Interfaces.C.Extensions

```
package Interfaces.C.Extensions is

   --  Definitions for C "void" and "void *" types
   subtype void     is System.Address;
   subtype void_ptr is System.Address;

   --  Definitions for C incomplete/unknown structs
   subtype opaque_structure_def is System.Address;
   type opaque_structure_def_ptr is access opaque_structure_def;

   --  Definitions for C++ incomplete/unknown classes
   subtype incomplete_class_def is System.Address;
   type incomplete_class_def_ptr is access incomplete_class_def;

   --  C bool
   type bool is new Boolean;
   pragma Convention (C, bool);

   --  64-bit integer types
   subtype long_long is Long_Long_Integer;
   type unsigned_long_long is mod 2 ** 64;

   -- (more not specified here)

end Interfaces.C.Extensions;
```

Interfaces.C.Pointers

```
generic
   type Index is (<>);
   type Element is private;
   type Element_Array is array (Index range <>) of aliased Element;
   Default_Terminator : Element;

package Interfaces.C.Pointers is

   type Pointer is access all Element;
   for Pointer'Size use System.Parameters.ptr_bits;

   function Value (Ref        : Pointer;
                   Terminator : Element := Default_Terminator)
                   return Element_Array;
   function Value (Ref    : Pointer;
                   Length : ptrdiff_t)
                   return Element_Array;

   Pointer_Error : exception;

   function "+" (Left : Pointer;   Right : ptrdiff_t) return Pointer;
   function "+" (Left : ptrdiff_t; Right : Pointer)   return Pointer;
   function "-" (Left : Pointer;   Right : ptrdiff_t) return Pointer;
   function "-" (Left : Pointer;   Right : Pointer)   return ptrdiff_t;

   procedure Increment (Ref : in out Pointer);
   procedure Decrement (Ref : in out Pointer);

   -- (more not specified here)

end Interfaces.C.Pointers;
```

Interfaces.C.Strings

```
package Interfaces.C.Strings is

   type char_array_access is access all char_array;
   for char_array_access'Size use System.Parameters.ptr_bits;

   type chars_ptr is private;

   type chars_ptr_array is array (size_t range <>) of aliased chars_ptr;

   Null_Ptr : constant chars_ptr;

   function To_Chars_Ptr (Item      : char_array_access;
                          Nul_Check : Boolean := False) return chars_ptr;

   function New_Char_Array (Chars : char_array) return chars_ptr;

   function New_String (Str : String) return chars_ptr;

   procedure Free (Item : in out chars_ptr);

   function Value (Item : chars_ptr) return char_array;
   function Value (Item   : chars_ptr;
                   Length : size_t)
                   return char_array;
   function Value (Item : chars_ptr) return String;
   function Value (Item   : chars_ptr;
                   Length : size_t)
                   return String;

   function Strlen (Item : chars_ptr) return size_t;

   -- (more not specified here)

end Interfaces.C.Strings;
```

Lab

Interfacing with C Lab

- Requirements
  - Given a C function that calculates speed in MPH from some information, your application should
    - Ask user for distance and time
    - Populate the structure appropriately
    - Call C function to return speed
    - Print speed to console
- Hints
  - Structure contains the following fields
    - Distance (floating point)
    - Distance Type (enumeral)
    - Seconds (floating point)

Interfacing with C Lab - GNAT Studio

To compile/link the C file into the Ada executable:

1. Make sure the C file is in the same directory as the Ada source files
2. Edit → Project Properties
3. Sources → Languages → Check the "C" box
4. Build and execute as normal

Interfacing with C Lab Solution - Ada

```
with Ada.Text_IO; use Ada.Text_IO;
with Interfaces.C;
procedure Main is

   package Float_Io is new Ada.Text_IO.Float_IO (Interfaces.C.C_float);

   One_Minute_In_Seconds : constant := 60.0;
   One_Hour_In_Seconds   : constant := 60.0 * One_Minute_In_Seconds;

   type Distance_T is (Feet, Meters, Miles) with Convention => C;
   type Data_T is record
      Distance      : Interfaces.C.C_float;
      Distance_Type : Distance_T;
      Seconds       : Interfaces.C.C_float;
   end record with Convention => C;
   function C_Miles_Per_Hour (Data : Data_T) return Interfaces.C.C_float
      with Import, Convention => C, External_Name => "miles_per_hour";

   Object_Feet : constant Data_T :=
     (Distance => 6_000.0,
      Distance_Type => Feet,
      Seconds  => One_Minute_In_Seconds);
   Object_Meters : constant Data_T :=
     (Distance => 3_000.0,
      Distance_Type => Meters,
      Seconds  => One_Hour_In_Seconds);
   Object_Miles : constant Data_T :=
     (Distance => 1.0,
      Distance_Type =>
      Miles, Seconds => 1.0);

   procedure Run (Object : Data_T) is
   begin
      Float_Io.Put (Object.Distance);
      Put (" " & Distance_T'Image (Object.Distance_Type) & " in ");
      Float_Io.Put (Object.Seconds);
      Put (" seconds = ");
      Float_Io.Put (C_Miles_Per_Hour (Object));
      Put_Line (" mph");
   end Run;

begin
   Run (Object_Feet);
   Run (Object_Meters);
   Run (Object_Miles);
end Main;
```

Interfacing with C Lab Solution - C

```c
enum DistanceT { FEET, METERS, MILES };
struct DataT {
    float distance;
    enum DistanceT distanceType;
    float seconds;
    };

float miles_per_hour ( struct DataT data ) {
   float miles = data.distance;
   switch ( data.distanceType ) {
      case METERS:
         miles = data.distance / 1609.344;
         break;
      case FEET:
         miles = data.distance / 5280.0;
         break;
   };
   return miles / ( data.seconds / ( 60.0 * 60.0 ) );
}
```

Summary

Summary

- Possible to interface with other languages (typically C)
- Ada provides some built-in support to make interfacing simpler
- Crossing languages can be made safer
  - But it still increases complexity of design / implementation

Tasking

Introduction

A Simple Task

- Parallel code execution via **task**
- `limited` types (No copies allowed)

```
procedure Main is
   task type Put_T;
   task body Put_T is
   begin
      loop
         delay 1.0;
         Put_Line ("T");
      end loop;
   end Put_T;

   T : Put_T;
begin -- Main task body
   loop
      delay 1.0;
      Put_Line ("Main");
   end loop;
end;
```

Two Synchronization Models

- Active
  - Rendezvous
  - **Client / Server** model
  - Server **entries**
  - Client **entry calls**
- Passive
  - **Protected objects** model
  - Concurrency-safe **semantics**

Tasks

Rendezvous Definitions

- **Server** declares several `entry`
- Client calls entries like subprograms
- Server `accept` the client calls
- At each standalone `accept`, server task **blocks**
  - **Until** a client calls the related `entry`

```
task type Msg_Box_T is
   entry Start;
   entry Receive_Message (S : String);
end Msg_Box_T;

task body Msg_Box_T is
begin
   loop
      accept Start;
      Put_Line ("start");

      accept Receive_Message (S : String) do
         Put_Line (S);
      end Receive_Message;
   end loop;
end Msg_Box_T;
```

Rendezvous Entry Calls

- Upon calling an `entry`, client **blocks**
  - **Until** server reaches `end` of its `accept` block

```
Put_Line ("calling start");
T.Start;
Put_Line ("calling receive 1");
T.Receive_Message ("1");
Put_Line ("calling receive 2");
T.Receive_Message ("2");
```

- May be executed as follows:

```
calling start
start                -- May switch place with line below
calling receive 1 -- May switch place with line above
Receive 1
calling receive 2
-- Blocked until another task calls Start
```

Accepting a Rendezvous

- `accept` statement
  - Wait on single entry
  - If entry call waiting: Server handles it
  - Else: Server **waits** for an entry call
- `select` statement
  - **Several** entries accepted at the **same time**
  - Can **time-out** on the wait
  - Can be **not blocking** if no entry call waiting
  - Can **terminate** if no clients can **possibly** make entry call
  - Can **conditionally** accept a rendezvous based on a **guard expression**

Protected Objects

Protected Objects

- **Multitask-safe** accessors to get and set state
- **No** direct state manipulation
- **No** concurrent modifications
- `limited` types (No copies allowed)

```
protected type
  Protected_Value is
   procedure Set (V : Integer);
   function Get return Integer;
private
   Value : Integer;
end Protected_Value;
```

```
protected body Protected_Value is
   procedure Set (V : Integer) is
   begin
      Value := V;
   end Set;

   function Get return Integer is
   begin
      return Value;
   end Get;
end Protected_Value;
```

.

Protected: Functions and Procedures

- A `function` can **get** the state
  - Protected data is **read-only**
  - Concurrent call to `function` is **allowed**
  - **No** concurrent call to `procedure`
- A `procedure` can **set** the state
  - **No** concurrent call to either `procedure` or `function`
- In case of concurrency, other callers get **blocked**
  - Until call finishes

Delays

Delay keyword

- `delay` keyword part of tasking
- Blocks for a time
- Relative: Blocks for at least `Duration`
- Absolute: Blocks until a given `Calendar.Time` or `Real_Time.Time`

```
with Calendar;

procedure Main is
   Relative : Duration := 1.0;
   Absolute : Calendar.Time
     := Calendar.Time_Of (2030, 10, 01);
begin
   delay Relative;
   delay until Absolute;
end Main;
```

Task and Protected Types

Task Activation

- Instantiated tasks start running when **activated**
- On the **stack**
  - When **enclosing** declarative part finishes **elaborating**
- On the **heap**
  - **Immediately** at instantiation

```
task type First_T is ...
type First_T_A is access all First_T;

task body First_T is ...
...
declare
   V1 : First_T;
   V2 : First_T_A;
begin  -- V1 is activated
   V2 := new First_T;  -- V2 is activated immediately
```

Single Declaration

- Instanciate an **anonymous** task (or protected) type
- Declares an object of that type
  - Body declaration is then using the **object** name

```
task Msg_Box is
    -- Msg_Box task is declared *and* instanciated
   entry Receive_Message (S : String);
end Msg_Box;

task body Msg_Box is
begin
   loop
      accept Receive_Message (S : String) do
         Put_Line (S);
      end Receive_Message;
   end loop;
end Msg_Box;
```

Task Scope

- Nesting is possible in **any** declarative block
- Scope has to **wait** for tasks to finish before ending
- At library level: program ends only when **all tasks** finish

```
package P is
   task type T;
end P;

package body P is
   task body T is
      loop
         delay 1.0;
         Put_Line ("tick");
      end loop;
   end T;

   Task_Instance : T;
end P;
```

Some Advanced Concepts

Waiting On Multiple Entries

- `select` can wait on multiple entries
  - With **equal** priority, regardless of declaration order

```
loop
  select
    accept Receive_Message (V : String)
    do
      Put_Line ("Message : " & String);
    end Receive_Message;
  or
    accept Stop;
    exit;
  end select;
end loop;
...
T.Receive_Message ("A");
T.Receive_Message ("B");
T.Stop;
```

Waiting With a Delay

- A `select` statement may **time-out** using `delay` or `delay until`
  - Resume execution at next statement
- Multiple `delay` allowed
  - Useful when the value is not hard-coded

```
loop
  select
    accept Receive_Message (V : String) do
      Put_Line ("Message : " & String);
    end Receive_Message;
  or
    delay 50.0;
    Put_Line ("Don't wait any longer");
    exit;
  end select;
end loop;
```

Calling an Entry With a Delay Protection

- A call to `entry` **blocks** the task until the entry is `accept` 'ed
- Wait for a **given amount of time** with `select ... delay`
- Only **one** entry call is allowed
- No `accept` statement is allowed

```
task Msg_Box is
   entry Receive_Message (V : String);
end Msg_Box;

procedure Main is
begin
   select
      Msg_Box.Receive_Message ("A");
   or
      delay 50.0;
   end select;
end Main;
```

Non-blocking Accept or Entry

- Using `else`
  - Task **skips** the `accept` or `entry` call if they are **not ready** to be entered
- `delay` is **not** allowed in this case

```
select
   accept Receive_Message (V : String) do
      Put_Line ("Received : " & V);
   end Receive_Message;
else
   Put_Line ("Nothing to receive");
end select;

[...]

select
   T.Receive_Message ("A");
else
   Put_Line ("Receive message not called");
end select;
```

Queue

- Protected `entry` or `procedure` and tasks `entry` are activated by **one** task at a time
- **Mutual exclusion** section
- Other tasks trying to enter are **queued**
  - In **First-In First-Out** (FIFO) by default
- When the server task **terminates**, tasks still queued receive `Tasking_Error`

Advanced Tasking

Other constructions are available

- **Guard condition** on `accept`
- `requeue` to **defer** handling of an `entry` call
- `terminate` the task when no `entry` call can happen anymore
- `abort` to stop a task immediately
- `select ... then abort` some other task

Lab

Tasking Lab

- Requirements
  - Create multiple tasks with the following attributes
    - Startup entry receives some identifying information and a delay length
    - Stop entry will end the task
    - Until stopped, the task will send it's identifying information to a monitor periodically based on the delay length
  - Create a protected object that stores the identifying information of task that called it
  - Main program should periodically check the protected object, and print when it detects a task switch
    - I.e. If the current task is different than the last printed task, print the identifying information for the current task

Tasking Lab Solution - Protected Object

```
with Task_Type;
package Protected_Object is
   protected Monitor is
      procedure Set (Id : Task_Type.Task_Id_T);
      function Get return Task_Type.Task_Id_T;
   private
      Value : Task_Type.Task_Id_T;
   end Monitor;
end Protected_Object;

package body Protected_Object is
   protected body Monitor is
      procedure Set (Id : Task_Type.Task_Id_T) is
      begin
         Value := Id;
      end Set;
      function Get return Task_Type.Task_Id_T is (Value);
   end Monitor;
end Protected_Object;
```

Tasking Lab Solution - Task Type

```
package Task_Type is
   type Task_Id_T is range 1_000 .. 9_999;
   task type Task_T is
      entry Start_Task (Task_Id        : Task_Id_T;
                        Delay_Duration : Duration);
      entry Stop_Task;
   end Task_T;
end Task_Type;

with Protected_Object;
package body Task_Type is
   task body Task_T is
      Wait_Time : Duration;
      Id        : Task_Id_T;
   begin
      accept Start_Task (Task_Id        : Task_Id_T;
                         Delay_Duration : Duration) do
         Wait_Time := Delay_Duration;
         Id        := Task_Id;
      end Start_Task;
      loop
         select
            accept Stop_Task;
            exit;
         or
            delay Wait_Time;
            Protected_Object.Monitor.Set (Id);
         end select;
      end loop;
   end Task_T;
end Task_Type;
```

Tasking Lab Solution - Main

```
with Ada.Text_IO; use Ada.Text_IO;
with Protected_Object;
with Task_Type;
procedure Main is
   T1, T2, T3       : Task_Type.Task_T;
   Last_Id, This_Id : Task_Type.Task_Id_T := Task_Type.Task_Id_T'last;
   use type Task_Type.Task_Id_T;
begin

   T1.Start_Task (1_111, 0.3);
   T2.Start_Task (2_222, 0.5);
   T3.Start_Task (3_333, 0.7);

   for Count in 1 .. 20 loop
      This_Id := Protected_Object.Monitor.Get;
      if Last_Id /= This_Id then
         Last_Id := This_Id;
         Put_Line (Count'image & "> " & Last_Id'image);
      end if;
      delay 0.2;
   end loop;

   T1.Stop_Task;
   T2.Stop_Task;
   T3.Stop_Task;

end Main;
```

Summary

Summary

- Tasks are **language-based** multi-threading mechanisms
  - Not necessarily for **truly** parallel operations
  - Originally for task-switching / time-slicing
- Multiple mechanisms to **synchronize** tasks
  - Delay
  - Rendezvous
  - Queues
  - Protected Objects

Subprogram Contracts

Introduction

Design-By-Contract

- Source code acting in roles of **client** and **supplier** under a binding **contract**
  - *Contract* specifies *requirements* and *guarantees*
    - *"A specification of a software element that affects its use by potential clients."* (Bertrand Meyer)
  - *Supplier* provides services
    - In Ada: Implements a subprogram
    - Guarantees specific functional behavior
    - Has requirements for guarantees to hold
  - *Client* utilizes services
    - In Ada: Calls the subprogram
    - Guarantees supplier's conditions are met
    - Requires result to follow the subprogram's guarantees

Ada Contracts

- Ada contracts include enforcement
  - At compile-time: specific constructs, features, and rules
  - At run-time: language-defined and user-defined exceptions
- Facilities prior to Ada 2012
  - Range specifications
  - Parameter modes
  - Generic contracts
  - OOP `interface` types (Ada 2005)
  - Work well, but on a restricted set of use-cases
- Contracts are explicitly added in **Ada 2012**
  - Carried by subprograms
  - ... or by types (seen later)
  - Can have **arbitrary** conditions, more **polyvalent**

Assertion

- Boolean expression expected to be `True`
- Said *to hold* when `True`
- Language-defined **`pragma`**

```
pragma Assert (not Full (Stack));
-- stack is not full
pragma Assert (Stack_Length = 0,
               Message => "stack was not empty");
-- stack is empty
```

- Raises language-defined `Assertion_Error` exception if expression does not hold

```
package Ada.Assertions is
  Assertion_Error : exception;
  procedure Assert (Check : in Boolean);
  procedure Assert (Check : in Boolean; Message : in String);
end Ada.Assertions;
```

Defensive Programming

- Should be replaced by subprogram contracts when possible

```
procedure Push (S : Stack) is
   Entry_Length : Positive := Length (S);
begin
   pragma Assert (not Is_Full (S)); -- entry condition
   [...]
   pragma Assert (Length (S) = Entry_Length + 1); -- exit condition
end Push;
```

- Subprogram contracts are an **assertion** mechanism
  - **Not** a drop-in replacement for all defensive code

```
procedure Force_Acquire (P : Peripheral) is
begin
   if not Available (P) then
      -- Corrective action
      Force_Release (P);
      pragma Assert (Available (P));
   end if;

   Acquire (P);
end;
```

Quiz

Which of the following statements is/are correct?

A. Contract principles apply only to Ada 2012
B. Contract should hold even for unique conditions and corner cases
C. Contract principles were first implemented in Ada
D. You cannot be both supplier and client

Quiz

Which of the following statements is/are correct?

A. Contract principles apply only to Ada 2012
B. ***Contract should hold even for unique conditions and corner cases***
C. Contract principles were first implemented in Ada
D. You cannot be both supplier and client

Explanations

A. No, but design-by-contract can be **explicitly** used in Ada 2012
B. Yes, special case should be included in the contract

Quiz

Which of the following statements is/are correct?

A. Contract principles apply only to Ada 2012
B. Contract should hold even for unique conditions and corner cases
C. Contract principles were first implemented in Ada
D. You cannot be both supplier and client

Explanations

A. No, but design-by-contract can be **explicitly** used in Ada 2012
B. Yes, special case should be included in the contract
C. No, in eiffel, in 1986!

Quiz

Which of the following statements is/are correct?

A. Contract principles apply only to Ada 2012
B. Contract should hold even for unique conditions and corner cases
C. Contract principles were first implemented in Ada
D. You cannot be both supplier and client

Explanations

A. No, but design-by-contract can be **explicitly** used in Ada 2012
B. Yes, special case should be included in the contract
C. No, in eiffel, in 1986!
D. No, in fact you are always **both**, even the `Main` has a caller!

Quiz

Which of the following statements is/are correct?

A. Assertions can be used in declarations
B. Assertions can be used in expressions
C. Any corrective action should happen before contract checks
D. Assertions must be checked using `pragma Assert`

Quiz

Which of the following statements is/are correct?

A. ***Assertions can be used in declarations***
B. Assertions can be used in expressions
C. ***Any corrective action should happen before contract checks***
D. Assertions must be checked using `pragma Assert`

Explanations

A. Will be checked at elaboration
B. No assertion expression, but `raise` expression exists

Quiz

Which of the following statements is/are correct?

A. Assertions can be used in declarations
B. Assertions can be used in expressions
C. Any corrective action should happen before contract checks
D. Assertions must be checked using `pragma Assert`

Explanations

A. Will be checked at elaboration
B. No assertion expression, but `raise` expression exists
C. Exceptions as flow-control adds complexity, prefer a proactive `if` to a (reactive) `exception` handler

Quiz

Which of the following statements is/are correct?

A. Assertions can be used in declarations
B. Assertions can be used in expressions
C. Any corrective action should happen before contract checks
D. Assertions must be checked using `pragma Assert`

Explanations

A. Will be checked at elaboration
B. No assertion expression, but `raise` expression exists
C. Exceptions as flow-control adds complexity, prefer a proactive `if` to a (reactive) `exception` handler
D. You can call `Ada.Assertions.Assert`, or even directly `raise Assertion_Error`

Quiz

Which of the following statements is/are correct?

A. Defensive coding is a good practice
B. Contracts can replace all defensive code
C. Contracts are executable constructs
D. Having exhaustive contracts will prevent runtime errors

Quiz

Which of the following statements is/are correct?

A. ***Defensive coding is a good practice***
B. Contracts can replace all defensive code
C. Contracts are executable constructs
D. Having exhaustive contracts will prevent runtime errors

Explanations

A. Principles are sane, contracts extend those
B. See previous slide example

Quiz

Which of the following statements is/are correct?

A. Defensive coding is a good practice
B. Contracts can replace all defensive code
C. Contracts are executable constructs
D. Having exhaustive contracts will prevent runtime errors

Explanations

A. Principles are sane, contracts extend those
B. See previous slide example
C. e.g. generic contracts are resolved at compile-time

Quiz

Which of the following statements is/are correct?

A. Defensive coding is a good practice
B. Contracts can replace all defensive code
C. Contracts are executable constructs
D. Having exhaustive contracts will prevent runtime errors

Explanations

A. Principles are sane, contracts extend those
B. See previous slide example
C. e.g. generic contracts are resolved at compile-time
D. A failing contract **will cause** a runtime error, only extensive (dynamic / static) analysis of contracted code may provide confidence in the absence of runtime errors (AoRTE)

Preconditions and Postconditions

Subprogram-based Assertions

- **Explicit** part of a subprogram's **specification**
  - Unlike defensive code
- *Precondition*
  - Assertion expected to hold **prior to** subprogram call
- *Postcondition*
  - Assertion expected to hold **after** subprogram return
- Requirements and guarantees on both supplier and client
- Syntax uses **aspects**

```
procedure Push (This : in out Stack_T;
                Value : Content_T)
  with Pre  => not Full (This),
       Post => not Empty (This)
               and Top (This) = Value;
```

Requirements / Guarantees: Quiz

- Given the following piece of code

```
procedure Start is
begin
    ...
    Turn_On;
    ...

procedure Turn_On
 with Pre => Has_Power,
      Post => Is_On;
```

- Complete the table in terms of requirements and guarantees

	Client (`Start`)	Supplier (`Turn_On`)
Pre (`Has_Power`)		
Post (`Is_On`)		

Requirements / Guarantees: Quiz

- Given the following piece of code

```
procedure Start is
begin
    ...
    Turn_On;
    ...

procedure Turn_On
 with Pre => Has_Power,
      Post => Is_On;
```

- Complete the table in terms of requirements and guarantees

	Client (`Start`)	Supplier (`Turn_On`)
Pre (`Has_Power`)	Requirement	Guarantee
Post (`Is_On`)	Guarantee	Requirement

Examples

```
package Stack_Pkg is
   procedure Push (Item : in Integer) with
         Pre  => not Full,
         Post => not Empty and then Top = Item;
   procedure Pop (Item : out Integer) with
         Pre  => not Empty,
         Post => not Full;
   function Pop return Integer with
         Pre  => not Empty,
         Post => not Full;
   function Top return Integer with
         Pre => not Empty;
   function Empty return Boolean;
   function Full return Boolean;
end Stack_Pkg;

package body Stack_Pkg is
   Values  : array (1 .. 100) of Integer;
   Current : Natural := 0;

   -- Push/Pop cannot fail because preconditions prevent it
   procedure Push (Item : in Integer) is
   begin
      Current          := Current + 1;
      Values (Current) := Item;
   end Push;

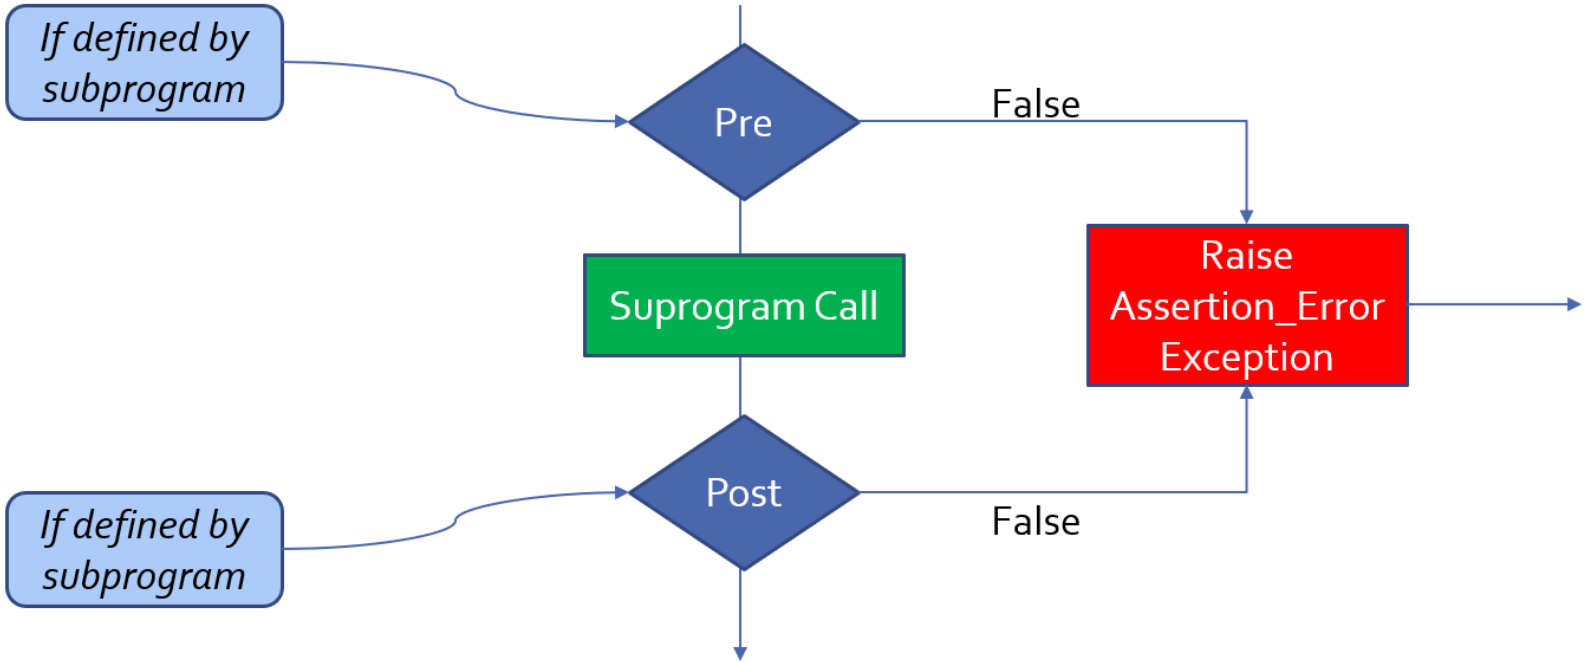
   procedure Pop (Item : out Integer) is
   begin
      Item    := Values (Current);
      Current := Current - 1;
   end Pop;

   function Pop return Integer is
      Item : constant Integer := Values (Current);
   begin
      Current := Current - 1;
      return Item;
   end Pop;

   function Top return Integer is (Values (Current));
   function Empty return Boolean is (Current not in Values'Range);
   function Full return Boolean is (Current >= Values'Length);
end Stack_Pkg;
```

Pre/Postcondition Semantics

- Calls inserted automatically by compiler



Contract with Quantified Expression

- Pre- and post-conditions can be **arbitrary** `Boolean` expressions

```
type Status_Flag is ( Power, Locked, Running );

procedure Clear_All_Status (
    Unit : in out Controller)
  -- guarantees no flags remain set after call
  with Post => (for all Flag in Status_Flag =>
    not Status_Indicated (Unit, Flag));

function Status_Indicated (
    Unit : Controller;
    Flag : Status_Flag)
    return Boolean;
```

Visibility for subprogram contracts

- **Any** visible name
  - All of the subprogram's **parameters**
  - Can refer to functions **not yet specified**
    - Must be declared in same scope
    - Different elaboration rules for expression functions

```
function Top (This : Stack) return Content
  with Pre => not Empty (This);
function Empty (This : Stack) return Boolean;
```

- `Post` has access to special attributes
  - See later

Preconditions and Postconditions Example

- Multiple aspects separated by commas

```
procedure Push (This : in out Stack;
                Value : Content)
  with Pre  => not Full (This),
       Post => not Empty (This) and Top (This) = Value;
```

(Sub)Types Allow Simpler Contracts

- Pre-condition

```
procedure Compute_Square_Root (Input : Integer;
                               Result : out Natural)
  with Pre  => Input >= 0,
       Post => (Result * Result) <= Input and
               (Result + 1) * (Result + 1) > Input;
```

- Subtype

```
procedure Compute_Square_Root (Input  : Natural;
                               Result : out Natural)
   with
       -- "Pre => Input >= 0" not needed
       -- (Input can't be < 0)
       Post => (Result * Result) <= Input and
               (Result + 1) * (Result + 1) > Input;
```

Quiz

```
function Area (L : Positive; H : Positive) return Positive is
   (L * H)
with Pre => ?
```

Which pre-condition is necessary for `Area` to calculate the correct result for all values `L` and `H`

A. `L > 0 and H > 0`
B. `L < Positive'Last and H < Positive'Last`
C. `L * H in Positive`
D. None of the above

Quiz

```
function Area (L : Positive; H : Positive) return Positive is
   (L * H)
with Pre => ?
```

Which pre-condition is necessary for `Area` to calculate the correct result for all values `L` and `H`

A. `L > 0 and H > 0`
B. `L < Positive'Last and H < Positive'Last`
C. `L * H in Positive`
D. ***None of the above***

Explanations

A. Parameters are `Positive`, so this is unnecessary
B. `L = Positive'Last and H = Positive'Last` will cause an overflow
C. Classic trap: the check itself may cause an overflow!

Preventing an overflow requires using the expression `Integer'Last / L <= H`

Special Attributes

Evaluate An Expression on Subprogram Entry

- Post-conditions may require knowledge of a subprogram's **entry context**

```
procedure Increment (This : in out Integer)
 with Post => ??? -- how to assert incrementation of `This`?
```

- Language-defined attribute `'Old`
- Expression is **evaluated** at subprogram entry
  - After pre-conditions check
  - Makes a copy
    - `limited` types are forbidden
    - May be expensive
  - Expression can be **arbitrary**
    - Typically `in out` parameters and globals

```
procedure Increment (This : in out Integer) with
    Pre  => This < Integer'Last,
    Post => This = This'Old + 1;
```

Example for Attribute 'Old

```
Global : String := Init_Global;
...
procedure Shift_And_Advance (Index : in out Integer) is
begin
   Global (Index) := Global (Index + 1);
   Index          := Index + 1;
end Shift_And_Advance;
```

- Note the different uses of **'Old** in the postcondition

```
procedure Shift_And_Advance (Index : in out Integer) with Post =>
   -- call At_Index before call
   Global (Index)'Old
      -- look at Index position in Global before call
      = Global'Old (Index'Old)
   and
   -- call At_Index after call with original Index
   Global (Index'Old)
      -- look at Index position in Global after call
      = Global (Index);
```

Error on conditional Evaluation of 'Old

- This code is **incorrect**

```
procedure Clear_Character (In_String : in out String;
                           At_Position : Positive)
   with Post => (if Found_At in In_String'Range
                 then In_String (Found_At)'Old = ' ');
```

- Copies `In_String (Found_At)` on entry
  - Will raise an exception on entry if `Found_At not in In_String'Range`
  - The postcondition's `if` check is not sufficient
- Solution requires a full copy of `In_String`

```
procedure Clear_Character (In_String : in out String;
                           At_Position : Positive)
   with Post => (if Found_At in In_String'Range
                 then In_String'Old (Found_At) = ' ');
```

Postcondition Usage of Function Results

- `function` result can be manipulated with `'Result`

```
function Greatest_Common_Denominator (A, B : Integer)
  return Integer with
    Pre  =>  A > 0 and B > 0,
    Post =>  Is_GCD (A, B,
                     Greatest_Common_Denominator'Result);
```

Quiz

```
type Index_T is range 1 .. 100;
-- Database initialized such that value for element at I = I
Database : array (Index_T) of Integer;
-- Set the value for element Index to Value and
-- then increment Index by 1
function Set_And_Move (Value :        Integer;
                       Index : in out Index_T)
                       return Boolean
   with Post => ...
```

Given the following expressions, what is their value if they are evaluated in the postcondition of the call `Set_And_Move (-1, 10)`

`Database'Old (Index)`
`Database (Index`Old)`
`Database (Index)'Old`

Quiz

```
type Index_T is range 1 .. 100;
-- Database initialized such that value for element at I = I
Database : array (Index_T) of Integer;
-- Set the value for element Index to Value and
-- then increment Index by 1
function Set_And_Move (Value :        Integer;
                       Index : in out Index_T)
                       return Boolean
   with Post => ...
```

Given the following expressions, what is their value if they are evaluated in the postcondition of the call `Set_And_Move (-1, 10)`

`Database'Old (Index)`	11	Use new index in copy of original Database
`Database (Index`Old)`	-1	Use copy of original index in current Database
`Database (Index)'Old`	10	Evaluation of Database (Index) before call

Examples

```
package Stack_Pkg is
   procedure Push (Item : in Integer) with
         Pre  => not Full,
         Post => not Empty and then Top = Item;
   procedure Pop (Item : out Integer) with
         Pre  => not Empty,
         Post => not Full and Item = Top'Old;
   function Pop return Integer with
         Pre  => not Empty,
         Post => not Full and Pop'Result = Top'Old;
   function Top return Integer with
         Pre => not Empty;
   function Empty return Boolean;
   function Full return Boolean;
end Stack_Pkg;

package body Stack_Pkg is
   Values  : array (1 .. 100) of Integer;
   Current : Natural := 0;

   -- Push/Pop cannot fail because preconditions prevent it
   procedure Push (Item : in Integer) is
   begin
      Current          := Current + 1;
      Values (Current) := Item;
   end Push;

   procedure Pop (Item : out Integer) is
   begin
      Item    := Values (Current);
      Current := Current - 1;
   end Pop;

   function Pop return Integer is
      Item : constant Integer := Values (Current);
   begin
      Current := Current - 1;
      return Item;
   end Pop;

   function Top return Integer is (Values (Current));
   function Empty return Boolean is (Current not in Values'Range);
   function Full return Boolean is (Current >= Values'Length);
end Stack_Pkg;
```

In Practice

Pre/Postconditions: To Be or Not To Be

- **Preconditions** are reasonable **default** for runtime checks
- **Postconditions** advantages can be **comparatively** low
  - Use of `'Old` and `'Result` with (maybe deep) copy
  - Very useful in **static analysis** contexts (Hoare triplets)
- For **trusted** library, enabling **preconditions only** makes sense
  - Catch **user's errors**
  - Library is trusted, so `Post => True` is a reasonable expectation
- Typically contracts are used for **validation**
- Enabling subprogram contracts in production may be a valid trade-off depending on...
  - Exception failure **trace availability** in production
  - Overall **timing constraints** of the final application
  - Consequences of violations **propagation**
  - Time and space **cost** of the contracts
- Typically production settings favour telemetry and off-line analysis

No Secret Precondition Requirements

- Client should be able to **guarantee** them
- Enforced by the compiler

```
package P is
   function Foo return Bar
     with Pre => Hidden; -- illegal private reference
private
   function Hidden return Boolean;
end P;
```

Postconditions Are Good Documentation

```
procedure Reset
    (Unit : in out DMA_Controller;
     Stream : DMA_Stream_Selector)
  with Post =>
    not Enabled (Unit, Stream) and
    Operating_Mode (Unit, Stream) = Normal_Mode and
    Selected_Channel (Unit, Stream) = Channel_0 and
    not Double_Buffered (Unit, Stream) and
    Priority (Unit, Stream) = Priority_Low and
    (for all Interrupt in DMA_Interrupt =>
        not Interrupt_Enabled (Unit, Stream, Interrupt));
```

Postcondition Compared to Their Body

- Specifying relevant properties will "repeat" the body
  - Unlike preconditions
  - Typically **simpler** than the body
  - Closer to a **re-phrasing** than a tautology
- Fit well *hard to solve and easy to check* problems
  - Solvers: `Solve (Find_Root'Result, Equation) = 0`
  - Search: `Can_Exit (Path_To_Exit'Result, Maze)`
  - Cryptography:
    `Match (Signer (Sign_Certificate'Result), Key.Public_Part)`
- Bad fit for poorly-defined or self-defining programs

```
function Get_Magic_Number return Integer
    with Post => Get_Magic_Number'Result = 42
    -- Useless post-condition, simply repeating the body
    is (42);
```

Postcondition Compared to Their Body: Example

```
function Greatest_Common_Denominator (A, B : Integer)
  return Integer with
  Pre  =>  A > 0 and B > 0,
  Post =>  Is_GCD (A, B, Greatest_Common_Denominator'Result);

function Greatest_Common_Denominator (A, B : Integer)
  return Integer is

function Is_GCD (A, B, Candidate : Integer)
    return Boolean is
  (A rem Candidate = 0 and
   B rem Candidate = 0 and
   (for all K in 1 .. Integer'Min (A,B) =>
      (if (A rem K = 0 and B rem K = 0)
       then K <= Candidate)));
```

Contracts Code Reuse

- Contracts are about **usage** and **behaviour**
  - Not optimization
  - Not implementation details
  - **Abstraction** level is typically high
- Extracting them to `function` is a good idea
  - *Code as documentation, executable specification*
  - Completes the **interface** that the client has access to
  - Allows for **code reuse**

```
procedure Withdraw (This   : in out Account;
                    Amount :        Currency) with
  Pre  => Open (This) and Funds_Available (This, Amount),
  Post => Balance (This) = Balance (This)'Old - Amount;
...
function Funds_Available (This   : Account;
                          Amount : Currency)
                          return Boolean is
    (Amount > 0.0 and then Balance (This) >= Amount)
  with Pre => Open (This);
```

- A `function` may be unavoidable
  - Referencing private type components

Subprogram Contracts on Private Types

```
package P is
  type T is private;
  procedure Q (This : T) with
    Pre => This.Total > 0; -- not legal
  ...
  function Current_Total (This : T) return Integer;
  ...
  procedure R (This : T) with
    Pre => Current_Total (This) > 0; -- legal
  ...
private
  type T is record
    Total : Natural ;
    ...
  end record;
  function Current_Total (This : T) return Integer is
      (This.Total);
end P;
```

Preconditions Or Explicit Checks?

- Any requirement from the spec should be a pre-condition
  - If clients need to know the body, abstraction is **broken**
- With pre-conditions

```
type Stack (Capacity : Positive) is tagged private;
procedure Push (This : in out Stack;
                Value : Content) with
  Pre  => not Full (This);
```

- With defensive code, comments, and return values

```
-- returns True iif push is successful
function Try_Push (This : in out Stack;
                   Value : Content) return Boolean
begin
  if Full (This) then
      return False;
  end if;
  ...
```

- But not both
  - For the implementation, preconditions are a **guarantee**
  - A subprogram body should **never** test them

Assertion Policy

- Pre/postconditions can be controled with
  `pragma Assertion_Policy`

```
pragma Assertion_Policy
     (Pre => Check,
      Post => Ignore);
```

- Fine **granularity** over assertion kinds and policy identifiers

https://docs.adacore.com/gnat_rm-docs/html/gnat_rm/gnat_rm/implementation_defined_pragmas.html#pragma-assertion-policy

- Certain advantage over explicit checks which are **harder** to disable
  - Conditional compilation via global `constant Boolean`

```
procedure Push (This : in out Stack;  Value : Content) is
begin
  if Debugging then
    if Full (This) then
      raise Overflow;
    end if;
  end if;
```

Lab

Subprogram Contracts Lab

- Overview
  - Create a priority-based queue ADT
    - Higher priority items come off queue first
    - When priorities are same, process entries in order received
- Requirements
  - Main program should verify pre-condition failure(s)
    - At least one pre-condition should raise something other than assertion error
  - Post-condition should ensure queue is correctly ordered
- Hints
  - Basically a stack, except insertion doesn't necessarily happen at "top"
  - To enable assertions in the run-time from GNAT Studio
    - Edit → Project Properties
    - **Build** → **Switches** → **Ada**
    - Click on *Enable assertions*

Subprogram Contracts Lab Solution - Queue (Spec)

```
with Ada.Strings.Unbounded; use Ada.Strings.Unbounded;
package Priority_Queue is
   Overflow : exception;
   type Priority_T is (Low, Medium, High);
   type Queue_T is tagged private;

   procedure Push (Queue    : in out Queue_T;
                   Priority :        Priority_T;
                   Value    :        String) with
      Pre => (not Full (Queue) and then Value'Length > 0) or else raise Overflow,
      Post => Valid (Queue);
   procedure Pop (Queue : in out Queue_T;
                  Value :    out Unbounded_String) with
      Pre  => not Empty (Queue),
      Post => Valid (Queue);

   function Full (Queue : Queue_T) return Boolean;
   function Empty (Queue : Queue_T) return Boolean;
   function Valid (Queue : Queue_T) return Boolean;
private
   Max_Queue_Size : constant := 10;
   type Entries_T is record
      Priority : Priority_T;
      Value    : Unbounded_String;
   end record;
   type Size_T is range 0 .. Max_Queue_Size;
   type Queue_Array_T is array (1 .. Size_T'Last) of Entries_T;
   type Queue_T is tagged record
      Size    : Size_T := 0;
      Entries : Queue_Array_T;
   end record;

   function Full (Queue : Queue_T) return Boolean is (Queue.Size = Size_T'Last);
   function Empty (Queue : Queue_T) return Boolean is (Queue.Size = 0);

   function Valid (Queue : Queue_T) return Boolean is
     (if Queue.Size <= 1 then True
      else (for all Index in 2 .. Queue.Size =>
               Queue.Entries (Index).Priority >=
               Queue.Entries (Index - 1).Priority));
end Priority_Queue;
```

Subprogram Contracts Lab Solution - Queue (Body)

```
package body Priority_Queue is

   procedure Push (Queue    : in out Queue_T;
                   Priority :        Priority_T;
                   Value    :        String) is
      Last      : Size_T renames Queue.Size;
      New_Entry : Entries_T := (Priority, To_Unbounded_String (Value));
   begin
      if Queue.Size = 0 then
         Queue.Entries (Last + 1) := New_Entry;
      elsif Priority < Queue.Entries (1).Priority then
         Queue.Entries (2 .. Last + 1) := Queue.Entries (1 .. Last);
         Queue.Entries (1) := New_Entry;
      elsif Priority > Queue.Entries (Last).Priority then
         Queue.Entries (Last + 1) := New_Entry;
      else
         for Index in 1 .. Last loop
            if Priority <= Queue.Entries (Index).Priority then
               Queue.Entries (Index + 1 .. Last + 1) := Queue.Entries (Index .. Last);
               Queue.Entries (Index)     := New_Entry;
               exit;
            end if;
         end loop;
      end if;
      Last := Last + 1;
   end Push;

   procedure Pop (Queue : in out Queue_T;
                  Value :    out Unbounded_String) is
   begin
      Value      := Queue.Entries (Queue.Size).Value;
      Queue.Size := Queue.Size - 1;
   end Pop;

end Priority_Queue;
```

Subprograms Contracts Lab Solution - Main

```
with Ada.Strings.Unbounded; use Ada.Strings.Unbounded;
with Ada.Text_IO;           use Ada.Text_IO;
with Priority_Queue;
procedure Main is
   Queue : Priority_Queue.Queue_T;
   Value : Unbounded_String;
begin

   for Count in 1 .. 3 loop
      for Priority in Priority_Queue.Priority_T'Range
      loop
         Queue.Push (Priority, Priority'Image & Count'Image);
      end loop;
   end loop;

   while not Queue.Empty loop
      Queue.Pop (Value);
      Put_Line (To_String (Value));
   end loop;

   for Count in 1 .. 4 loop
      for Priority in Priority_Queue.Priority_T'Range
      loop
         Queue.Push (Priority, Priority'Image & Count'Image);
      end loop;
   end loop;

end Main;
```

Summary

Contract-Based Programming Benefits

- Facilitates building software with reliability built-in
  - Software cannot work well unless "well" is carefully defined
  - Clarifies design by defining obligations/benefits
- Enhances readability and understandability
  - Specification contains explicitly expressed properties of code
- Improves testability but also likelihood of passing!
- Aids in debugging
- Facilitates tool-based analysis
  - Compiler checks conformance to obligations
  - Static analyzers (e.g., SPARK, CodePeer) can verify explicit precondition and postconditions

Summary

- Based on viewing source code as clients and suppliers with enforced obligations and guarantees
- No run-time penalties unless enforced
- OOP introduces the tricky issues
  - Inheritance of preconditions and postconditions, for example
- Note that pre/postconditions can be used on concurrency constructs too

	Clients	Suppliers
Preconditions	Obligation	Guarantee
Postconditions	Guarantee	Obligation

Type Contracts

Introduction

Strong Typing

- We know Ada supports strong typing

```
type Small_Integer_T is range -1_000 .. 1_000;
type Enumerated_T is (Sun, Mon, Tue, Wed, Thu, Fri, Sat);
type Array_T is array (1 .. 3) of Boolean;
```

- But what if we need stronger enforcement?
  - Number must be even
  - Subet of non-consecutive enumerals
  - Array should always be sorted
- **Type Invariant**
  - Property of type that is always true on external reference
  - *Guarantee* to client, similar to subprogram postcondition
- **Subtype Predicate**
  - Add more complicated constraints to a type
  - Always enforced, just like other constraints

Type Invariants

Examples

```
package Bank is
   type Account_T is private with Type_Invariant => Consistent_Balance (Account_T);
   type Currency_T is delta 0.01 digits 12;
   function Consistent_Balance (This : Account_T) return Boolean;
   procedure Open (This : in out Account_T; Initial_Deposit : Currency_T);
private
   type List_T is array (1 .. 100) of Currency_T;
   type Transaction_List_T is record
      Values : List_T;
      Count  : Natural := 0;
   end record;
   type Account_T is record -- initial state MUST satisfy invariant
      Current_Balance : Currency_T := 0.0;
      Withdrawals     : Transaction_List_T;
      Deposits        : Transaction_List_T;
   end record;
end Bank;

package body Bank is
   function Total (This : Transaction_List_T) return Currency_T is
      Result : Currency_T := 0.0;
   begin
      for I in 1 .. This.Count loop -- no iteration if list empty
         Result := Result + This.Values (I);
      end loop;
      return Result;
   end Total;
   function Consistent_Balance (This : Account_T) return Boolean is
      ( Total (This.Deposits) - Total (This.Withdrawals) = This.Current_Balance );
   procedure Open (This : in out Account_T; Initial_Deposit : Currency_T) is
   begin
      This.Current_Balance := Initial_Deposit;
      -- if we checked, the invariant would be false here!
      This.Withdrawals.Count   := 0;
      This.Deposits.Count      := 1;
      This.Deposits.Values (1) := Initial_Deposit;
   end Open; -- invariant is now true
end Bank;
```

Type Invariants

- There may be conditions that must hold over entire lifetime of objects
  - Pre/postconditions apply only to subprogram calls
- Sometimes low-level facilities can express it

```
subtype Weekdays is Days range Mon .. Fri;

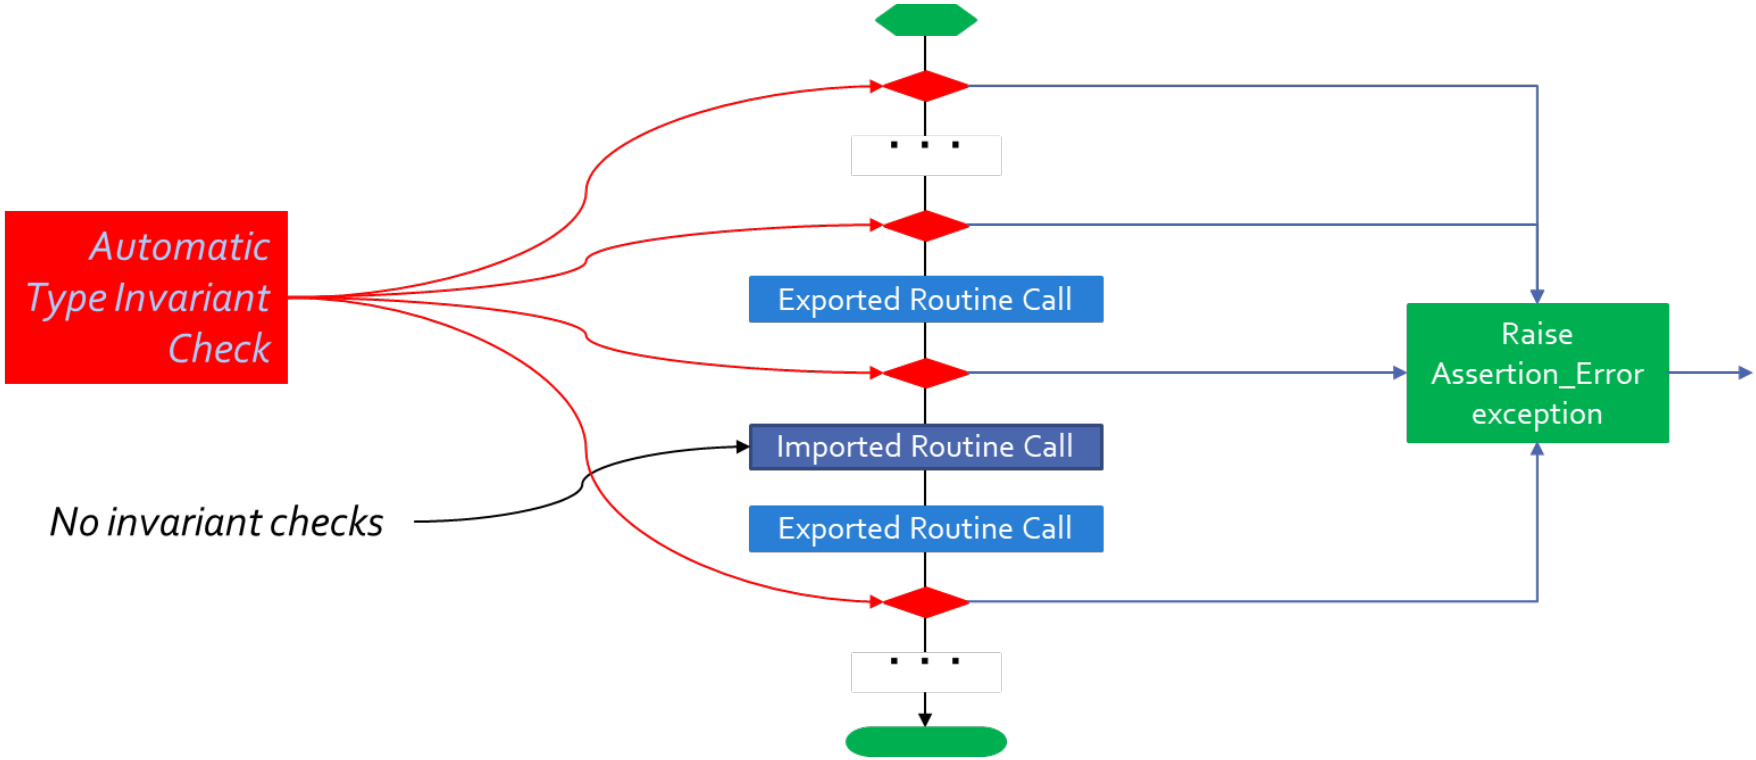
-- Guaranteed (absent unchecked conversion)
Workday : Weekdays := Mon;
```

- Type invariants apply across entire lifetime for complex abstract data types
- Part of ADT concept, so only for private types

Type Invariant Verifications

- Automatically inserted by compiler
- Evaluated as postcondition of creation, evaluation, or return object
  - When objects first created
  - Assignment by clients
  - Type conversions
    - Creates new instances
- Not evaluated on internal state changes
  - Internal routine calls
  - Internal assignments
- Remember - these are abstract data types

Invariant Over Object Lifetime (Calls)



Example Type Invariant

- A bank account balance must always be consistent
  - Consistent Balance: Total Deposits - Total Withdrawals = Balance

```
package Bank is
   type Account is private with
     Type_Invariant => Consistent_Balance (Account);
   ...
   -- Called automatically for all Account objects
   function Consistent_Balance (This : Account)
     return Boolean;
   ...
private
   ...
end Bank;
```

Example Type Invariant Implementation

```
package body Bank is
...
  function Total (This : Transaction_List)
      return Currency is
    Result : Currency := 0.0;
  begin
    for Value of This loop -- no iteration if list empty
      Result := Result + Value;
    end loop;
    return Result;
  end Total;
  function Consistent_Balance (This : Account)
      return Boolean is
  begin
    return Total (This.Deposits) - Total (This.Withdrawals)
           = This.Current_Balance;
  end Consistent_Balance;
end Bank;
```

Invariants Don't Apply Internally

- No checking within supplier package
  - Otherwise there would be no way to implement anything!
- Only matters when clients can observe state

```
procedure Open (This : in out Account;
                Name : in String;
                Initial_Deposit : in Currency) is
begin
   This.Owner := To_Unbounded_String (Name);
   This.Current_Balance := Initial_Deposit;
   -- invariant would be false here!
   This.Withdrawals := Transactions.Empty_List;
   This.Deposits := Transactions.Empty_List;
   This.Deposits.Append (Initial_Deposit);
   -- invariant is now true
end Open;
```

Default Type Initialization for Invariants

- Invariant must hold for initial value
- May need default type initialization to satisfy requirement

```
package P is
   -- Type is private, so we can't use Default_Value here
   type T is private with Type_Invariant => Zero (T);
   procedure Op (This : in out T);
   function Zero (This : T) return Boolean;
private
   -- Type is not a record, so we need to use aspect
   -- (A record could use default values for its components)
   type T is new Integer with Default_Value => 0;
   function Zero (This : T) return Boolean is
   begin
      return (This = 0);
   end Zero;
end P;
```

Type Invariant Clause Placement

- Can move aspect clause to private part

```
package P is
   type T is private;
   procedure Op (This : in out T);
private
   type T is new Integer with
     Type_Invariant => T = 0,
     Default_Value => 0;
end P;
```

- It is really an implementation aspect
  - Client shouldn't care!

Invariants Are Not Foolproof

- Access to ADT representation via pointer could allow back door manipulation
- These are private types, so access to internals must be granted by the private type's code
- Granting internal representation access for an ADT is a highly questionable design!

Quiz

```
package P is
   type Some_T is private;
   procedure Do_Something (X : in out Some_T);
private
   function Counter (I : Integer) return Boolean;
   type Some_T is new Integer with
      Type_Invariant => Counter (Integer (Some_T));
end P;

package body P is
   function Local_Do_Something (X : Some_T)
                                return Some_T is
      Z : Some_T := X + 1;
   begin
      return Z;
   end Local_Do_Something;
   procedure Do_Something (X : in out Some_T) is
   begin
      X := X + 1;
      X := Local_Do_Something (X);
   end Do_Something;
   function Counter (I : Integer)
                     return Boolean is
      ( True );
end P;
```

If **Do_Something** is called from outside of P, how many times is **Counter** called?

A. 1
B. 2
C. 3
D. 4

Quiz

```
package P is
   type Some_T is private;
   procedure Do_Something (X : in out Some_T);
private
   function Counter (I : Integer) return Boolean;
   type Some_T is new Integer with
      Type_Invariant => Counter (Integer (Some_T));
end P;

package body P is
   function Local_Do_Something (X : Some_T)
                                return Some_T is
      Z : Some_T := X + 1;
   begin
      return Z;
   end Local_Do_Something;
   procedure Do_Something (X : in out Some_T) is
   begin
      X := X + 1;
      X := Local_Do_Something (X);
   end Do_Something;
   function Counter (I : Integer)
                     return Boolean is
      ( True );
end P;
```

If **Do_Something** is called from outside of P, how many times is **Counter** called?

A. 1
B. *2*
C. 3
D. 4

Type Invariants are only evaluated on entry into and exit from externally visible subprograms. So `Counter` is called when entering and exiting `Do_Something` - not `Local_Do_Something`, even though a new instance of `Some_T` is created

Subtype Predicates

Examples

```
with Ada.Exceptions; use Ada.Exceptions;
with Ada.Text_IO;    use Ada.Text_IO;
procedure Predicates is

   subtype Even_T is Integer with Dynamic_Predicate => Even_T mod 2 = 0;
   type Serial_Baud_Rate_T is range 110 .. 115_200 with
      Static_Predicate => Serial_Baud_Rate_T in -- Non-contiguous range
          2_400 | 4_800 | 9_600 | 14_400 | 19_200 | 28_800 | 38_400 | 56_000;

   -- This must be dynamic because "others" will be evaluated at run-time
   subtype Vowel_T is Character with Dynamic_Predicate =>
         (case Vowel_T is when 'A' | 'E' | 'I' | 'O' | 'U' => True, when others => False);

   type Table_T is array (Integer range <>) of Integer;
   subtype Sorted_Table_T is Table_T (1 .. 5) with
        Dynamic_Predicate =>
        (for all K in Sorted_Table_T'Range =>
           (K = Sorted_Table_T'First or else Sorted_Table_T (K - 1) <= Sorted_Table_T (K)));

   J      : Even_T;
   Values : Sorted_Table_T := (1, 3, 5, 7, 9);

begin
   begin
      Put_Line ("J is" & J'Image);
      J := Integer'Succ (J); -- assertion failure here
      Put_Line ("J is" & J'Image);
      J := Integer'Succ (J); -- or maybe here
      Put_Line ("J is" & J'Image);
   exception
      when The_Err : others =>
         Put_Line (Exception_Message (The_Err));
   end;

   for Baud in Serial_Baud_Rate_T loop
      Put_Line (Baud'Image);
   end loop;

   Put_Line (Vowel_T'Image (Vowel_T'Succ ('A')));
   Put_Line (Vowel_T'Image (Vowel_T'Pred ('Z')));

   begin
      Values (3) := 0; -- not an exception
      Values     := (1, 3, 0, 7, 9); -- exception
   exception
      when The_Err : others =>
         Put_Line (Exception_Message (The_Err));
   end;
end Predicates;
```

Subtype Predicates Concept

- Ada defines support for various kinds of constraints
  - Range constraints
  - Index constraints
  - Others...
- Language defines rules for these constraints
  - All range constraints are contiguous
  - Matter of efficiency
- **Subtype predicates** generalize possibilities
  - Define new kinds of constraints

Predicates

- Something asserted to be true about some subject
  - When true, said to "hold"
- Expressed as any legal boolean expression in Ada
  - Quantified and conditional expressions
  - Boolean function calls
- Two forms in Ada
  - **Static Predicates**
    - Specified via aspect named **Static_Predicate**
  - **Dynamic Predicates**
    - Specified via aspect named **Dynamic_Predicate**

Really, type and subtype Predicates

- Applicable to both
- Applied via aspect clauses in both cases
- Syntax

```
type name is type_definition
   with aspect_mark [ => expression] { ,
             aspect_mark [ => expression] }
subtype defining_identifier is subtype_indication
   with aspect_mark [ => expression] { ,
             aspect_mark [ => expression] }
```

Why Two Predicate Forms?

	Static	Dynamic
Content	More Restricted	Less Restricted
Placement	Less Restricted	More Restricted

- Static predicates can be used in more contexts
  - More restrictions on content
  - Can be used in places Dynamic Predicates cannot
- Dynamic predicates have more expressive power
  - Fewer restrictions on content
  - Not as widely available

Subtype Predicate Examples

- Dynamic Predicate

```
subtype Even is Integer with Dynamic_Predicate =>
   Even mod 2 = 0; -- Boolean expression
   -- (Even indicates "current instance")
```

- Static Predicate

```
type Serial_Baud_Rate is range 110 .. 115200
  with Static_Predicate => Serial_Baud_Rate  in
    -- Non-contiguous range
    110   | 300   | 600 | 1200 | 2400 | 4800 |
    9600 | 14400 | 19200 | 28800 | 38400 | 56000 |
    57600 | 115200;
```

Predicate Checking

- Calls inserted automatically by compiler
- Violations raise exception `Assertion_Error`
  - When predicate does not hold (evaluates to False)
- Checks are done before value change
  - Same as language-defined constraint checks
- Associated variable is unchanged when violation is detected

Predicate Checks Placement

- Anywhere value assigned that may violate target constraint
- Assignment statements
- Explicit initialization as part of object declaration
- Subtype conversion
- Parameter passing
  - All modes when passed by copy
  - Modes `in out` and `out` when passed by reference
- Implicit default initialization for record components
- On default type initialization values, when taken

References Are Not Checked

```
with Ada.Text_IO;   use Ada.Text_IO;
procedure Test is
  subtype Even is Integer with Dynamic_Predicate => Even mod 2 = 0;
  J, K : Even;
begin
  -- predicates are not checked here
  Put_Line ("K is" & K'Image);
  Put_Line ("J is" & J'Image);
  -- predicate is checked here
  K := J; -- assertion failure here
  Put_Line ("K is" & K'Image);
  Put_Line ("J is" & J'Image);
end Test;
```

- Output would look like

```
K is 1969492223
J is 4220029

raised SYSTEM.ASSERTIONS.ASSERT_FAILURE:
Dynamic_Predicate failed at test.adb:9
```

Predicate Expression Content

- Reference to value of type itself, i.e., "current instance"

```
subtype Even is Integer
  with Dynamic_Predicate => Even mod 2 = 0;
J, K : Even := 42;
```

- Any visible object or function in scope
  - Does not have to be defined before use
  - Relaxation of "declared before referenced" rule of linear elaboration
  - Intended especially for (expression) functions declared in same package spec

Static Predicates

- *Static* means known at compile-time, informally
  - Language defines meaning formally (RM 3.2.4)
- Allowed in contexts in which compiler must be able to verify properties
- Content restrictions on predicate are necessary

Allowed Static Predicate Content (1)

- Ordinary Ada static expressions
- Static membership test selected by current instance
- Example 1

```
type Serial_Baud_Rate is range 110 .. 115200
  with Static_Predicate => Serial_Baud_Rate in
    -- Non-contiguous range
    110   | 300   | 600   | 1200  | 2400  | 4800  | 9600 |
    14400 | 19200 | 28800 | 38400 | 56000 | 57600 | 115200;
```

- Example 2

```
type Days is (Sun, Mon, Tues, We, Thu, Fri, Sat);
 -- only way to create subtype of non-contiguous values
subtype Weekend is Days
  with Static_Predicate => Weekend in Sat | Sun;
```

Allowed Static Predicate Content (2)

- Case expressions in which dependent expressions are static and selected by current instance

```
type Days is (Sun, Mon, Tue, Wed, Thu, Fri, Sat);
subtype Weekend is Days with Static_Predicate =>
  (case Weekend is
   when Sat | Sun => True,
   when Mon .. Fri => False);
```

- Note: if-expressions are disallowed, and not needed

```
subtype Drudge is Days with Static_Predicate =>
  -- not legal
  (if Drudge in Mon .. Fri then True else False);
-- should be
subtype Drudge is Days with Static_Predicate =>
  Drudge in Mon .. Fri;
```

Allowed Static Predicate Content (3)

- A call to =, /=, <, <=, >, or >= where one operand is the current instance (and the other is static)
- Calls to operators `and`, `or`, `xor`, `not`
  - Only for pre-defined type **Boolean**
  - Only with operands of the above
- Short-circuit controls with operands of above
- Any of above in parentheses

Dynamic Predicate Expression Content

- Any arbitrary boolean expression
  - Hence all allowed static predicates' content
- Plus additional operators, etc.

```
subtype Even is Integer
  with Dynamic_Predicate => Even mod 2 = 0;
subtype Vowel is Character with Dynamic_Predicate =>
  (case Vowel is
   when 'A' | 'E' | 'I' | 'O' | 'U' => True,
   when others => False); -- evaluated at run-time
```

- Plus calls to functions
  - User-defined
  - Language-defined

Types Controlling For-Loops

- Types with dynamic predicates cannot be used
  - Too expensive to implement

```
subtype Even is Integer
  with Dynamic_Predicate => Even mod 2 = 0;
...
-- not legal - how many iterations?
for K in Even loop
   ...
end loop;
```

- Types with static predicates can be used

```
type Days is (Sun, Mon, Tues, We, Thu, Fri, Sat);
subtype Weekend is Days
  with Static_Predicate => Weekend in Sat | Sun;
-- Loop uses "Days", and only enters loop when in Weekend
-- So "Sun" is first value for K
for K in Weekend loop
   ...
end loop;
```

Why Allow Types with Static Predicates?

- Efficient code can be generated for usage

```
type Days is (Sun, Mon, Tues, We, Thu, Fri, Sat);
subtype Weekend is Days with Static_Predicate => Weekend in Sat | Sun;
...
for W in Weekend loop
  GNAT.IO.Put_Line (W'Image);
end loop;
```

- `for` loop generates code like

```
declare
  w : weekend := sun;
begin
  loop
    gnat__io__put_line__2 (w'Image);
    case w is
      when sun =>
        w := sat;
      when sat =>
        exit;
      when others =>
        w := weekend'succ(w);
    end case;
  end loop;
end;
```

In Some Cases Neither Kind Is Allowed

- No predicates can be used in cases where contiguous layout required
  - Efficient access and representation would be impossible
- Hence no array index or slice specification usage

```
type Play is array (Weekend) of Integer; -- illegal
type List is array (Days range <>) of Integer;
L : List (Weekend); -- not legal
```

Special Attributes for Predicated Types

- Attributes **'First_Valid** and **'Last_Valid**
  - Can be used for any static subtype
  - Especially useful with static predicates
  - **'First_Valid** returns smallest valid value, taking any range or predicate into account
  - **'Last_Valid** returns largest valid value, taking any range or predicate into account
- Attributes `'Range`, **'First** and **'Last** are not allowed
  - Reflect non-predicate constraints so not valid
  - `'Range` is just a shorthand for **'First** .. **'Last**
- **'Succ** and **'Pred** are allowed since work on underlying type

Initial Values Can Be Problematic

- Users might not initialize when declaring objects
  - Most predefined types do not define automatic initialization
  - No language guarantee of any specific value (random bits)
  - Example

```
subtype Even is Integer
  with Dynamic_Predicate => Even mod 2 = 0;
K : Even;   -- unknown (invalid?) initial value
```

- The predicate is not checked on a declaration when no initial value is given
- So can reference such junk values before assigned
  - This is not illegal (but is a bounded error)

Subtype Predicates Aren't Bullet-Proof

- For composite types, predicate checks apply to whole object values, not individual components

```
procedure Demo is
  type Table is array (1 .. 5) of Integer
    -- array should always be sorted
    with Dynamic_Predicate =>
      (for all K in Table'Range =>
        (K = Table'First or else Table(K-1) <= Table(K)));
  Values : Table := (1, 3, 5, 7, 9);
begin
  ...
  Values (3) := 0; -- does not generate an exception!
  ...
  Values := (1, 3, 0, 7, 9); -- does generate an exception
  ...
end Demo;
```

Beware Accidental Recursion In Predicate

- Involves functions because predicates are expressions
- Caused by checks on function arguments
- Infinitely recursive example

```
type Sorted_Table is array (1 .. N) of Integer with
   Dynamic_Predicate => Sorted (Sorted_Table);
-- on call, predicate is checked!
function Sorted (T : Sorted_Table) return Boolean;
```

- Non-recursive example

```
type Sorted_Table is array (1 .. N) of Integer with
   Dynamic_Predicate =>
   (for all K in Sorted_Table'Range =>
      (K = Sorted_Table'First
       or else Sorted_Table (K - 1) <= Sorted_Table (K)));
```

- Type-based example

```
type Table is array (1 .. N) of Integer;
subtype Sorted_Table is Table with
     Dynamic_Predicate => Sorted (Sorted_Table);
function Sorted (T : Table) return Boolean;
```

GNAT-Specific Aspect Name *Predicate*

- Conflates two language-defined names
- Takes on kind with widest applicability possible
  - Static if possible, based on predicate expression content
  - Dynamic if cannot be static
- Remember: static predicates allowed anywhere that dynamic predicates allowed
  - But not inverse
- Slight disadvantage: you don't find out if your predicate is not actually static
  - Until you use it where only static predicates are allowed

Enabling/Disabling Contract Verification

- Corresponds to controlling specific run-time checks
  - Syntax

```
pragma Assertion_Policy (policy_name);
pragma Assertion_Policy (
   assertion_name => policy_name
   {, assertion_name => policy_name} );
```

- Vendors may define additional policies (GNAT does)
- Default, without pragma, is implementation-defined
- Vendors almost certainly offer compiler switch
  - GNAT uses same switch as for pragma Assert: `-gnata`

Quiz

```
type Days_T is (Sun, Mon, Tue, Wed, Thu, Fri, Sat);
function Is_Weekday (D : Days_T) return Boolean is
   (D /= Sun and then D /= Sat);
```

Which of the following is a valid subtype predicate?

A.
```
subtype T is Days_T with
   Static_Predicate => T in Sun | Sat;
```

B.
```
subtype T is Days_T with Static_Predicate =>
   (if T = Sun or else T = Sat then True else False);
```

C.
```
subtype T is Days_T with
   Static_Predicate => not Is_Weekday (T);
```

D.
```
subtype T is Days_T with
   Static_Predicate =>
     case T is when Sat | Sun => True,
               when others => False;
```

Quiz

```
type Days_T is (Sun, Mon, Tue, Wed, Thu, Fri, Sat);
function Is_Weekday (D : Days_T) return Boolean is
   (D /= Sun and then D /= Sat);
```

Which of the following is a valid subtype predicate?

A.
```
subtype T is Days_T with
   Static_Predicate => T in Sun | Sat;
```

B.
```
subtype T is Days_T with Static_Predicate =>
   (if T = Sun or else T = Sat then True else False);
```

C.
```
subtype T is Days_T with
   Static_Predicate => not Is_Weekday (T);
```

D.
```
subtype T is Days_T with
   Static_Predicate =>
     case T is when Sat | Sun => True,
               when others => False;
```

Explanations

A. Correct
B. `If` statement not allowed in a predicate
C. Function call not allowed in `Static_Predicate` (this would be OK for `Dynamic_Predicate`)
D. Missing parentheses around `case` expression

Lab

Type Contracts Lab

- Overview
  - Create simplistic class scheduling system
    - Client will specify name, day of week, start time, end time
    - Supplier will add class to schedule
    - Supplier must also be able to print schedule
- Requirements
  - Monday, Wednesday, and/or Friday classes can only be 1 hour long
  - Tuesday and/or Thursday classes can only be 1.5 hours long
  - Classes without a set day meet for any non-negative length of time
- Hints
  - *Subtype Predicate* to create subtypes of day of week
  - *Type Invariant* to ensure that every class meets for correct length of time
  - To enable assertions in the run-time from GNAT Studio
    - Edit → Project Properties
    - **Build** → **Switches** → **Ada**
    - Click on *Enable assertions*

Type Contracts Lab Solution - Schedule (Spec)

```
with Ada.Strings.Unbounded; use Ada.Strings.Unbounded;
package Schedule is
   Maximum_Classes : constant := 24;
   type Days_T is (Mon, Tue, Wed, Thu, Fri, None);
   type Time_T is delta 0.5 range 0.0 .. 23.5;
   type Classes_T is tagged private;
   procedure Add_Class (Classes    : in out Classes_T;
                        Name       :        String;
                        Day        :        Days_T;
                        Start_Time :        Time_T;
                        End_Time   :        Time_T) with
                        Pre => Count (Classes) < Maximum_Classes;
   procedure Print (Classes : Classes_T);
   function Count (Classes : Classes_T) return Natural;
private
   subtype Short_Class_T is Days_T with Static_Predicate => Short_Class_T in Mon | Wed | Fri;
   subtype Long_Class_T is Days_T with Static_Predicate => Long_Class_T in Tue | Thu;
   type Class_T is tagged record
      Name       : Unbounded_String := Null_Unbounded_String;
      Day        : Days_T           := None;
      Start_Time : Time_T           := 0.0;
      End_Time   : Time_T           := 0.0;
   end record;
   subtype Class_Size_T is Natural range 0 .. Maximum_Classes;
   subtype Class_Index_T is Class_Size_T range 1 .. Class_Size_T'Last;
   type Class_Array_T is array (Class_Index_T range <>) of Class_T;
   type Classes_T is tagged record
      Size : Class_Size_T := 0;
      List : Class_Array_T (Class_Index_T);
   end record with Type_Invariant =>
      (for all Index in 1 .. Size => Valid_Times (Classes_T.List (Index)));

   function Valid_Times (Class : Class_T) return Boolean is
     (if Class.Day in Short_Class_T then Class.End_Time - Class.Start_Time = 1.0
      elsif Class.Day in Long_Class_T then Class.End_Time - Class.Start_Time = 1.5
      else Class.End_Time >= Class.Start_Time);

   function Count (Classes : Classes_T) return Natural is (Classes.Size);
end Schedule;
```

Type Contracts Lab Solution - Schedule (Body)

```
with Ada.Text_IO; use Ada.Text_IO;
package body Schedule is

   procedure Add_Class
     (Classes    : in out Classes_T;
      Name       :        String;
      Day        :        Days_T;
      Start_Time :        Time_T;
      End_Time   :        Time_T) is
   begin
      Classes.Size                := Classes.Size + 1;
      Classes.List (Classes.Size) :=
        (Name       => To_Unbounded_String (Name), Day => Day,
         Start_Time => Start_Time, End_Time => End_Time);
   end Add_Class;

   procedure Print (Classes : Classes_T) is
   begin
      for Index in 1 .. Classes.Size loop
         Put_Line
           (Days_T'Image (Classes.List (Index).Day) & ": " &
            To_String (Classes.List (Index).Name) & " (" &
            Time_T'Image (Classes.List (Index).Start_Time) & " -" &
            Time_T'Image (Classes.List (Index).End_Time) & " )");
      end loop;
   end Print;

end Schedule;
```

Type Contracts Lab Solution - Main

```
with Ada.Exceptions; use Ada.Exceptions;
with Ada.Text_IO;    use Ada.Text_IO;
with Schedule;       use Schedule;
procedure Main is
   Classes : Classes_T;
begin
   Classes.Add_Class (Name       => "Calculus",
                      Day        => Mon,
                      Start_Time => 10.0,
                      End_Time   => 11.0);
   Classes.Add_Class (Name       => "History",
                      Day        => Tue,
                      Start_Time => 11.0,
                      End_Time   => 12.5);
   Classes.Add_Class (Name       => "Biology",
                      Day        => Wed,
                      Start_Time => 13.0,
                      End_Time   => 14.0);
   Classes.Print;
   begin
      Classes.Add_Class (Name       => "Biology",
                         Day        => Thu,
                         Start_Time => 13.0,
                         End_Time   => 14.0);
   exception
      when The_Err : others =>
         Put_Line (Exception_Information (The_Err));
   end;
end Main;
```

Summary

Working with Type Invariants

- They are not fully foolproof
  - External corruption is possible
  - Requires dubious usage
- Violations are intended to be supplier bugs
  - But not necessarily so, since not always bullet-proof
- However, reasonable designs will be foolproof

Type Invariants vs Predicates

- Type Invariants are valid at external boundary
  - Useful for complex types - type may not be consistent during an operation
- Predicates are like other constraint checks
  - Checked on declaration, assignment, calls, etc

Ada 2022

What's New

Types Syntax

- Image and litterals
  - `'Image` improvements
  - User-defined literals
- Composite Types
  - Improved aggregates
  - Iteration filters

Standard Lib

- `Ada.Numerics.Big_Numbers`
- `Ada.Strings.Text_Buffers`
- `System.Atomic_Operations`

Miscellaneous

- Jorvik profile
- Target name symbol
- Enumeration representation
- Staticness
- C variadics
- Subprogram access contracts
- Declare expression
- Simpler renames

Miscellaneous

Miscellaneous (1/2)

- Target Name Symbol (`@`)

```
Count := @ + 1;
```

- Enumeration representation attributes

```
type E is (A => 10, B => 20);
...
E'Enum_Rep (A); -- 10
E'Enum_Val (10); -- A
```

  - `'Enum_Rep` already present in GNAT

- Staticness

```
subtype T is Integer range 0 .. 2;
function In_T (A : Integer)
   return Boolean is
   (A in T) with Static;
```

- C variadic functions interface

```
procedure printf (format : String; opt_param : int)
   with Import, Convention => C_Variadic_1; -- Note the 1 for a single arg
```

Miscellaneous (2/2)

- Contract on access types

```
type A_F is access function (I : Integer) return Integer
   with Post => A_F'Result > I;
```

- Declare expressions

```
Area : Float := (declare
                    Pi : constant Float := 3.14159
                 begin
                    (Pi ** 2) * R);
```

- More expressive renamings

```
A : Integer;
B renames A; -- B type is infered
```

Image and Literals

Generalized 'Image

- All types have a Image attribute
- Its return value is (mostly) standardized
  - Except for e.g. unchecked unions
- Non-exhaustive example
- Code

```
Put_Line
   (Record_Obj'Image);
Put_Line
   (Array_Obj'Image);
Put_Line
   (Acc_O'Image);
Put_Line
   (Task_Obj'Image);
```

- Output

```
(I =>  1)
[
 (I =>  1),
 (I =>  1),
 (I =>  1),
 (I =>  1)]
(access 7ffd360de7f0)
(task task_obj_000000000240C0B0)
```

User-defined Image

- User-defined types can have a Image attribute
  - Need to specify the Put_Image aspect

```
type My_Type
[...]
  with Put_Image => My_Put_Image;

procedure My_Put_Image
   (Buffer : in out
             Ada.Strings.Text_Buffers.Root_Buffer_Type'Class;
    Arg    : in T);
```

- Using the new package Text_Buffers

User-defined 'Image example

- `custom_image.ads`

```
type R is null record with
  Put_Image => My_Put_Image;
```

- `custom_image.adb`

```
procedure My_Put_Image
  (Output : in out
     Ada.Strings.Text_Buffers.Root_Buffer_Type'Class;
   Obj    : R)
is
begin
   Output.Put ("my very own null record");
end My_Put_Image;
```

User-defined literals

- User-defined types can accept literals as inputs
  - `Integer`, `Float`, or `String`
  - Specifying a constructor to `Integer_Literal` aspect (resp `Float`, `String`)
- `my_int.ads`

```
type My_Int_T is private
   with Integer_Literal => Make_0;

function Make_0 (S : String) return My_Int_T;
...
type My_Int_T is record
    I : Integer;
end record;

function Make_0 (S : String) return My_Int_T is ((I => 0));
```

- `main.adb`

```
I : My_Int_T := 1;
```

Composite Types

Square Bracket Array Aggregates

- Only for `array` aggregates
  - **Required** in Ada 2022
  - **Forbidden** otherwise
  - Not backwards-compatible

```
A : array (1 .. 1) of Integer := [99]; -- Legal
B : array (1 .. 1) of Integer := (99); -- Not legal
```

- Allows for more complex initialization

```
O3 : A := [for I in 1 .. 10
           => (if I * I > 1 and I * I < 20 then I else 0)];
```

Iteration filters

- For any iteration
- Using the **when** keyword

```
for J in 1 .. 100 when J mod 2 /= 0 loop
```

- Can be used for aggregates as well

```
O4 : A := (for I of O3 when I /= 0 => I);
```

Container aggregates

- Using `with Aggregate => (<Args>)`
- Args are
  - `Empty` init function (or else default)
  - `Add_Named` named aggregate element
  - `Add_Unnamed` positional aggregate element
- You **cannot** mix named and unnamed

```
type JSON_Array is private
  with Aggregate => (Empty       => New_JSON_Array,
                     Add_Unnamed => Append);

function New_JSON_Array return JSON_Array;

procedure Append
  (Self  : in out JSON_Array;
   Value : JSON_Value) is null;

List : JSON.JSON_Array := [1, 2, 3];
```

- Implemented on standard lib's containers

Delta aggregates

- Can build an object from another one
  - Similarly to tagged types' extension aggregates
  - Using `with delta` in the aggregate

```
type Arr is array (1 .. 2) of Integer;
A : Arr := [3, 4];
B : Arr := [A with delta 1 => 0];

type Rec is record
   I1, I2 : Integer;
end record;
C : Rec := (I1 => 3, I2 => 4);
D : Rec := (C with delta I1 => 0);
```

Standard Lib

Ada.Numerics.Big_Numbers

- Numbers of arbitary size
  - Particularly useful for cryptography
- Big_Integers, Big_Reals child packages

```
type Big_Integer is private
  with Integer_Literal => From_Universal_Image,
       Put_Image => Put_Image;
subtype Big_Positive is Big_Integer [...]
subtype Big_Natural is Big_Integer [...]
subtype Valid_Big_Integer is [...]

function To_Big_Integer (Arg : Integer) return Valid_Big_Integer;
```

- Comparison operators

```
function "=" (L, R : Valid_Big_Integer) return Boolean;
function "<" (L, R : Valid_Big_Integer) return Boolean;
[...]
```

- Arithmetic operators

```
function "abs" (L : Valid_Big_Integer) return Valid_Big_Integer;
function "+" (L, R : Valid_Big_Integer) return Valid_Big_Integer;
[...]
```

Ada.Strings.Text_Buffers

- Object-oriented package
- Root_Buffer_Type
  - Basically a text stream
  - Abstract object

```
type Root_Buffer_Type is abstract tagged private [...];

procedure Put (
  Buffer : in out Root_Buffer_Type;
  Item   : in     String) is abstract;

procedure Wide_Put (
  Buffer : in out Root_Buffer_Type;
  Item   : in     Wide_String) is abstract;

procedure Wide_Wide_Put (
  Buffer : in out Root_Buffer_Type;
  Item   : in     Wide_Wide_String) is abstract;

procedure Put_UTF_8 (
  Buffer : in out Root_Buffer_Type;
  Item   : in     UTF_Encoding.UTF_8_String) is abstract;
```

System.Atomic_Operations

- Atomic types
  - May be used for lock-free synchronization
- Several child packages
  - Exchange
    - `function Atomic_Exchange ...`
  - Test_And_Set
    - `function Atomic_Test_And_Set ...`
  - Integer_Arithmetic, and Modular_Arithmetic
    - `generic package`
    - `procedure Atomic_Add ...`

Jorvik Profile

- A **non-backwards compatible profile** based on Ravenscar
  - Defined in the RM D.13 (Ada 2022)
- Remove some constraints
  - Number of protected entries, entry queue length...
  - Scheduling analysis may be harder to perform
- Subset of Ravenscars' requirements
- `pragma Profile (Jorvik)`

Summary

Ada 2022

- Adapting to new usages
  - Cryptography
  - Lock-free synchronizations
- More expressive syntax
  - `'Image` and literals
  - Functional approach: filters...
  - Simplified declarations and renamings
- Some features are not implemented...
  - ...by anyone
  - Those are related to parallelization
  - And are subject to future specification change

Unimplemented

- Global states
  - Available in SPARK
  - Declare side-effect in spec
- `parallel` reserved word
  - Parallelizes code
  - Conflict checking
  - Chunked iterators
  - Procedural iterators
    - `My_Map.Iterate (My_Procedure'Access)`

Annex - Ada Version Comparison

Ada Evolution

- Ada 83
  - Development late 70s
  - Adopted ANSI-MIL-STD-1815 Dec 10, 1980
  - Adopted ISO/8652-1987 Mar 12, 1987
- Ada 95
  - Early 90s
  - First ISO-standard OO language
- Ada 2005
  - Minor revision (amendment)
- Ada 2012
  - The new ISO standard of Ada

Programming Structure, Modularity

	Ada 83	Ada 95	Ada 2005	Ada 2012
Packages	✓	✓	✓	✓
Child units		✓	✓	✓
Limited with and mutually dependent specs			✓	✓
Generic units	✓	✓	✓	✓
Formal packages		✓	✓	✓
Partial parameterization			✓	✓
Conditional/Case expressions				✓
Quantified expressions				✓
In-out parameters for functions				✓
Iterators				✓
Expression functions				✓

Object-Oriented Programming

	Ada 83	Ada 95	Ada 2005	Ada 2012
Derived types	✓	✓	✓	✓
Tagged types		✓	✓	✓
Multiple inheritance of interfaces			✓	✓
Named access types	✓	✓	✓	✓
Access parameters, Access to subprograms		✓	✓	✓
Enhanced anonymous access types			✓	✓
Aggregates	✓	✓	✓	✓
Extension aggregates		✓	✓	✓
Aggregates of limited type			✓	✓
Unchecked deallocation	✓	✓	✓	✓
Controlled types, Accessibility rules		✓	✓	✓
Accessibility rules for anonymous types			✓	✓
Contract programming				✓

Concurrency

	Ada 83	Ada 95	Ada 2005	Ada 2012
Tasks	✓	✓	✓	✓
Protected types, Distributed annex		✓	✓	✓
Synchronized interfaces			✓	✓
Delays, Timed calls	✓	✓	✓	✓
Real-time annex		✓	✓	✓
Ravenscar profile, Scheduling policies			✓	✓
Multiprocessor affinity, barriers				✓
Re-queue on synchronized interfaces				✓
Ravenscar for multiprocessor systems				✓

Standard Libraries

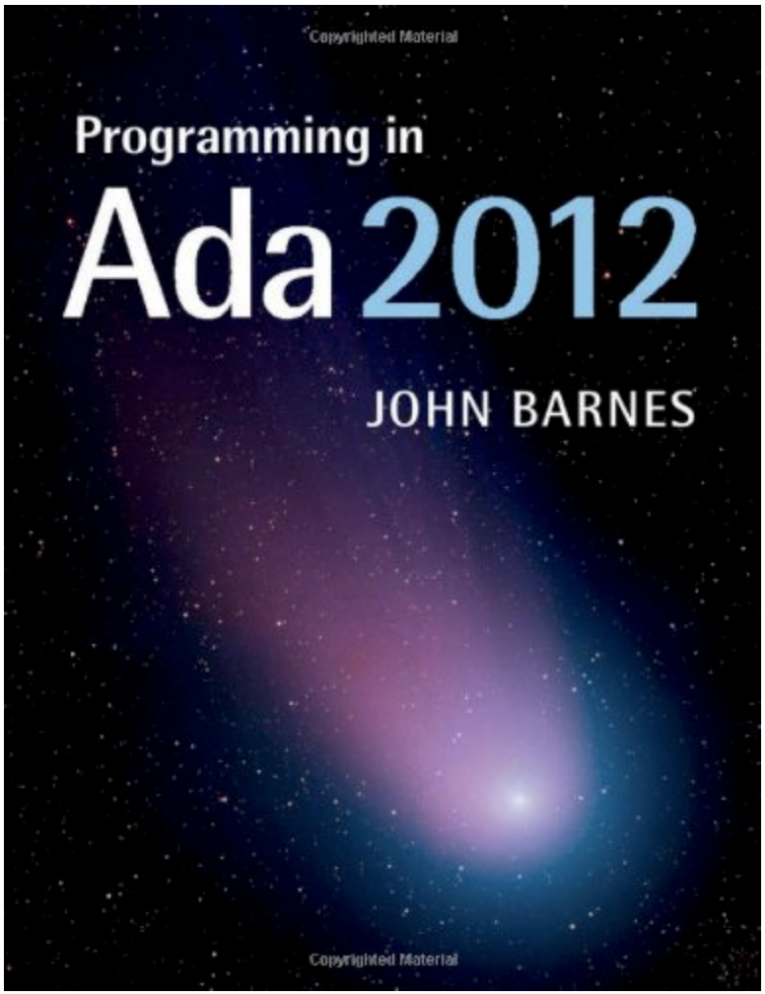
	Ada 83	Ada 95	Ada 2005	Ada 2012
Numeric types	✓	✓	✓	✓
Complex types		✓	✓	✓
Vector/matrix libraries			✓	✓
Input/output	✓	✓	✓	✓
Elementary functions		✓	✓	✓
Containers			✓	✓
Bounded Containers, holder containers, multiway trees				✓
Task-safe queues				✓
7-bit ASCII	✓	✓	✓	✓
8/16 bit		✓	✓	✓
8/16/32 bit (full Unicode)			✓	✓
String encoding package				✓

Annex - Reference Materials

General Ada Information

Learning the Ada Language

- Written as a tutorial for those new to Ada



Reference Manual

- **LRM** - Language Reference Manual (or just **RM**)
  - Always on-line (including all previous versions) at www.adaic.org
- Finding stuff in the RM
  - You will often see the RM cited like this **RM 4.5.3(10)**
  - This means *Section 4.5.3, paragraph 10*
  - Have a look at the table of contents
    - Knowing that chapter 5 is *Statements* is useful.
  - Index is very long, but very good!

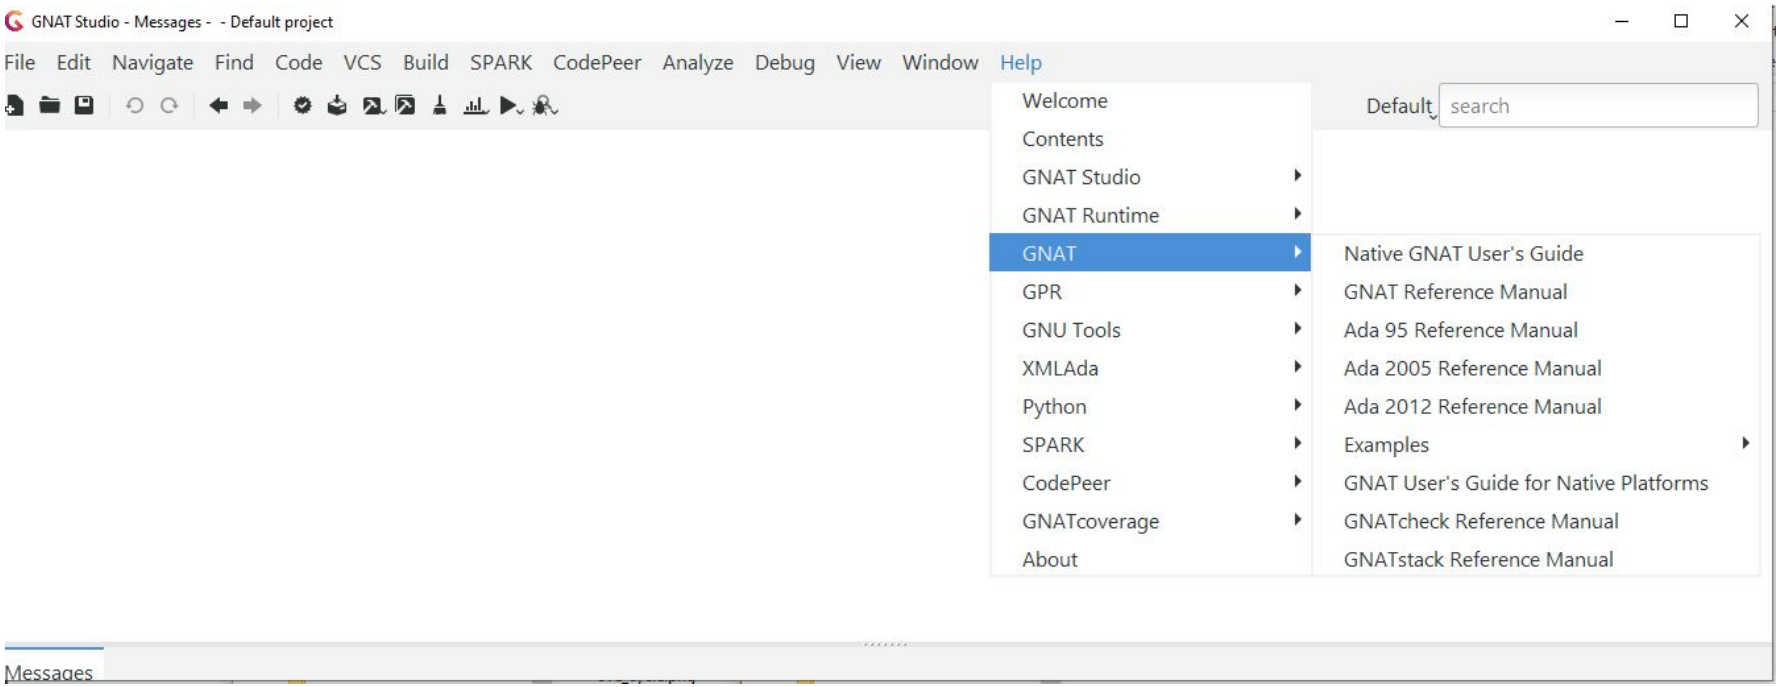
Current Ada Standard

- "ISO/IEC 8652(E) with Technical Corrigendum 1"
- Useful as a Reference Text but not intended to be read from beginning to end

GNAT-Specific Help

Reference Manual

- Reference Manual(s) available from GNAT Studio Help



GNAT Tools

- GNAT User's Guide
  - LOTS of info about the main tools: the GNAT compiler, binder, linker etc.
- GNAT Reference Manual
  - How GNAT implements Ada, pragmas, aspects, attributes etc. etc.
- GNAT Studio (the IDE)
  - Tutorial
  - User's Guide
  - Release notes
- Many other tools

AdaCore Support

Need More Help?

- If you have an AdaCore subscription:
  - Find out your customer number #XXXX
- Open a "TN" via the GNAT Tracker web interface and/or email.
  - Send to: support@gnat.com
  - Subject should read: #XXXX - (descriptive text)
    - Where XXXX is your customer number
- Not just for "bug reports"
  - Ask questions, make suggestions etc. etc.
